AN ILLUSTRATED SYNOPSIS OF THE PRINCIPAL LARVAL FORMS OF THE ORDER COLEOPTERA*

BY ADAM G. BÖVING,

SENIOR ENTOMOLOGIST, U. S. BUREAU OF ENTOMOLOGY

AND

F. C. CRAIGHEAD,

IN CHARGE OF FOREST INSECT INVESTIGATIONS, U. S. BUREAU OF
ENTOMOLOGY

* This study was projected about 1915 when both authors who were working independently on separate families of coleopterous larvae realized that it was practically impossible to go far in descriptive work within these families without having a comparative knowledge of the characters throughout the order. During the following five years the material of all the families represented in the collections of the Bureau of Entomology and of the United States National Museum was examined, family characterizations were prepared, and typical larval characters were illustrated. By 1920 a general scheme of the classification presented herewith was drawn up, including the keys to families and family series, and most of the plates were completed. Since 1923 one of the authors (Craighead) has been able to devote very little time to the work; the other author (Böving) has continued to give much time to it, has remodeled many of the keys, and has introduced those portions treating the subfamilies and lesser groups.

LARVAL FORMS OF COLEOPTERA

PREFACE

The character of this publication is double, both graphic and descriptive. It displays a series of habitus-figures and detail-drawings of typical larvae pertaining to the different families and subfamilies of the beetle order and it presents keys for their determination and classification.

The figures are all original with the exception of one copied from Schiödte's paper on the buprestid larvae^{1A} and two figures pertaining to *Hydrochus* from Avery Richmond's paper on the Hydrophilids,^{1B} which are properly accounted for in the explanation to plates 22 and 80. All the figures on plates 84 to 86 and most of the figures on plate 69 were drawn by Mr. J. A. Hyslop, the remainder by Mr. R. A. St. George and by one or the other of the authors, from specimens in alcohol or from slides with microscopic details present in the collection of beetle larvae in the United States National Museum. There will be found only a few figures of larvae belonging to the suborder Adephaga and to some of the series of the Polyphaga, such as the Cerambycoidea and the Scarabaeoidea, because the larvae of these groups have been particularly well and completely illustrated by former authors in generally known and in most cases easily available publications.

The descriptions in the keys are based on original studies of larval material at hand.

These keys are intended to serve not only as a practical means for the determination of beetle larvae, but also as a contribution to the taxonomic discussion of the natural systematic grouping of the Coleoptera.

In the selection of the systematic characters for the single series, families, and subfamilies preference has been given to those which are most easily observed and least variable throughout the individual groups and which at the same time express the taxonomic relationship between associated groups, thus making it possible in most cases to list these groups in a natural systematic sequence. Only in the series key (pp. 10-15) has it not been possible or, rather, not practical to do this.

As a rule the classification of the larvae agrees with the commonly recognized classification of the imagines, and particularly

LARVAL FORMS OF COLEOPTERA

well with the one followed in Leng's catalogue. In those cases, however, in which the characters of the larvae suggest a different systematic position of the group to which they belong than do the characters of their imagines, commentary remarks have been made in footnotes.

In a publication such as the present one in which the space limit must be a rather determining factor only a few characters can be used in the descriptions of the groups. As the field is new and rather uncultivated it is unavoidable that misleading or impracticable systematic characters have been introduced, or even that mistakes may have crept in. It is also realized that some of the figures, especially those which were prepared many years ago, when the authors were less familiar with the taxonomic value of the different characters, are not entirely satisfactory: in fact, scores of old figures have been discarded and new ones substituted. Frankly admitting the many shortcomings of the paper, of which nobody is more aware than the authors, it is nevertheless hoped that it may meet an evident desideratum in the entomological literature and encourage the taxonomic study of the beetle larvae, a study which still is in its beginning.

For obvious reasons no attempt has been made to compile a full bibliography, and such references to literature as are given will be found in footnotes. Neither has a complete explanation of terms been prepared, as the terms used in the keys as a rule are defined in the easily available "Glossary of Entomology" by John B. Smith, published by the Brooklyn Entomological Society in 1906, or have been defined and are in common use by modern entomological writers, the present authors included. The very few new terms found in the keys, such as "urogomphus," meaning a tail-projection, instead of "cercus" or "pseudoecercus," and "raster," meaning a rake, designated for the spinose region on the ventral side of the last abdominal segments in Scarabaeidae, will readily be understood through the examination of the figures themselves and the corresponding explanations.

Besides the strictly alternative characters of the keys, others, guiding but not necessarily alternative, are given in parentheses.

The generic and specific nomenclature used in the keys, and particularly in the explanations of plates, follows the one applied in Leng's catalogue^{1c} for the North American larvae, in Reitter's cata-

^{1c} Charles W. Leng: Catalogue of the Coleoptera of America, North of Mexico. 1920, with suppl. 1927.

LARVAL FORMS OF COLEOPTERA

logue^{1D} for the European larvae, and in Junk's catalogue^{1E} for the larvae from other countries.

It is impossible to adequately acknowledge and express our appreciation of the great amount of assistance we have received from many colleagues and friends interested in our project. The late Dr. E. A. Schwarz followed our work with interest and generous assistance, and we are deeply indebted to Doctor Schwarz for his suggestions as to the systematic position of many forms. From time to time in the last more than fifteen years Messrs. E. C. Rosenberg, J. P. Kryger, and K. L. Henriksen have presented one of the authors with many important Danish larvae, now included in the collection of the National Museum, without which it would have been impossible to characterize and figure the larval types of several families and subfamilies. An important collection of larvae from Finland, acquired last year through Prof. Unio Saalas, has been very useful for the final revision and completion of the keys. From the British Museum of Natural History a number of exceedingly interesting forms have been presented by Dr. C. J. Gahan and Dr. K. G. Blair. Dr. G. de Lapouge from France has donated a valuable collection of carabid larvae. Many meloid larvae and other larvae of great importance have come from Dr. A. Cros. Mr. J. C. M. Gardner has sent a great many named larvae from India; Dr. O. H. Swezey, larvae of Proterhinidae and other rare larval types from Honolulu; Dr. J. Bequaert, larvae of *Drilidae* and other remarkable larval types from Yucatan, Mexico, Liberia, and Belgian Congo; and Dr. J. G. Needham, a Chinese larva which appears as a transitional type between the Psephenidae and the Ptilodactylidae. Last but not least we have had available for daily study the large collection of beetle larvae in the United States National Museum, which gradually has been accumulated by numerous North American entomologists since the year 1896, when C. V. Riley transferred to the National Museum a small biological collection which he brought with him from Missouri. Now the collection contains invaluable systematic material from North and South America, collected and reared by E. A. Schwarz, H. G. Hubbard, H. S. Barber, A. D. Hopkins and his many associates, F. H. Chittenden, George Dimmock, C. C. Hamilton, J. A. Hyslop, J. J. Davis, A. B. Champlain, T. E. Snyder, R. T. Cotton, R. J. Sinn, and many other entomologists, and it is also

rich in material of European larvae which has been acquired by exchange between Prof. C. V. Riley and Dr. Fr. Meinert at the Zoological Museum in Copenhagen or has been bought, particularly from the collections of Wm. Schlick and K. W. Verhoeff.

Finally, the authors wish to extend their sincere thanks to Mr. R. A. St. George. For a number of years he has been giving a great deal of study to the larvae of the order, particularly the families of the Cucujoidea, and has assisted in the characterization of this series. At the same time he has made many of the drawings included in this paper.

LARVAL FORMS OF COLEOPTERA

INTRODUCTION

(pl. 125)

The coleopterous larvae belong to three fundamentally different types. Consequently, in the present synopsis the families are arranged into three different suborders, namely:

Suborder 1: Archostemata

Suborder 2: Adephaga

Suborder 3: Polyphaga

According to the views commonly held by entomologists,² only two major divisions of Coleoptera, the Adephaga and the Polyphaga, are recognized. However, the present studies, which intentionally stress larval characters and avoid consideration of imaginal structures, show the necessity of recognizing a third suborder for the inclusion of the Cupedidae and Micromalthidae, whose larval morphology isolates them from all other beetles. The term "Archostemata," first proposed by Kolbe, is here adopted as the subordinal name for these two families. Although very specialized they are nevertheless so ancient that they must be regarded as the representatives of an almost extinct larval type.

It is of great interest that several modern entomologists, working exclusively with the imagines, have realized the isolation of the Cupedidae and Micromalthidae; and Dr. Wm. T. M. Forbes, in his paper on wing-folding patterns of the Coleoptera (*Jour. New York Ent. Soc.*, vol. 34, 1926), has, like the present authors, recognized those two families as forming a separate suborder which he, too, names Archostemata.

In contrast to the primitive and slightly specialized larval types to which the Polyphaga can be traced, the larvae of the Adephaga possess a complex of highly advanced and derivative characters which probably have been acquired through a long evolutionary process from an unknown primitive larval type somewhat different from the existing primitive Polyphaga larva. However, the well developed and well defined tarsus of the Adephaga carrying one or two distinct and movable claws may be a primitive character not altered through the course of their development into high specialization. The ancient Archostemata larvae also possess a distinct tarsus and claw and

² Consult the introduction "Essay on Classification" in C. W. Leng's Catalogue, pp. 3-37, in which a very clear and critical review is given of the different systems from the earliest one by Linnaeus to the one proposed and applied by Leng himself. The bibliography is prepared with the painstaking care so characteristic of the author.

LARVAL FORMS OF COLEOPTERA

certain Polyphaga larvae (though not necessarily of primitive families) likewise show an indication of a separate tarsus and claw (see footnote 5, p. 9). In neuropterous larvae, as *Raphidia*, *Sialis*, and *Corydalis*, a distinct tarsus and two claws are present and in many other respects the greatest similarity exists between them and the typical Caraboidea. Unquestionably, however, these neuropterous larvae are less primitive than the primitive polyphagous Staphylinoidea (p. 25). It would therefore be logical to place the Adephaga as the third suborder, as it is the more modern of the three, and the Polyphaga before it, because the suborder Polyphaga includes existing larvae of a primitive type from which its other larval types can be derived directly or indirectly. But for practical purposes it appears more advisable to rank the suborders in the commonly accepted sequence, and as no traceable phylogenetic connection exists between them, the sequence in which they are placed and treated is rather immaterial.

The primitive type of the Polyphaga is found in its most characteristic and original form in the series Staphylinoidea as limited in the present paper, more particularly in such families and subfamilies as the Limnebiidae, Leptinidae, and Anisotomidae; and it is from the larval type found in these families that are derived not only the more or less specialized larvae of the other staphylinoid families but also the different types of the hydrophiloid larvae (p. 31), possibly through larvae of such families as Hydrochidae and Spercheidae.

The larva of the series Byrrhoidea (p. 43) represents a second distinct polyphagous type which, while primitive, is in some respects less primitive than the larva of the primitive Staphylinoidea. Probably the two series have ancestors in common, but by no larval type known up to this time are they linked together. However, some of the derived families of the byrrhoid type and some belonging to a third distinct polyphagous type, the cucujoid type, approach one another, and about the direct affinities between the Cucujoidea and the Staphylinoidea there can be no doubt. Rather isolated as the series Byrrhoidea appears in the polyphagous suborder, it does not seem necessary to rank it and the families and series derived from it as a separate suborder. Two series, the Dascilloidea (p. 43) and the Cleroidea (p. 55), are descended directly from the Byrrhoidea, supposedly through heterocerid forms and dermestid forms, respectively.

From the byrrhoid family the Byrrhidae (p. 43), the Dryopoidea (p. 44) can be derived through the dryopoid family Ptilo-

LARVAL FORMS OF COLEOPTERA

dactylidae; from the dryopoid family Eurypogonidae, the Elateroidea (p. 49) may wholly or partly branch; from near this same dryopoid family, or more probably from different Dryopoidea, the Cantharoidea and very likely a minor part of the Elateroidea have come; and from the dascillloid family Dascillidae, the series Scarabaeoidea (p. 51) descends according to their larval forms through scarabaeoid families like the Trogidae and the Lucanidae.

With the cleroid family Ciidae (p. 55) may be associated the series Mordelloidea (p. 60), the series Bostrichoidea (p. 62), and the so-called phytophagous assemblage of different series, including the Cerambyeoidea (p. 60), Chrysomeloidea (p. 63), Platystomoidea (p. 66), and Curculionoidea (p. 66). The Meloidea (p. 58) may also belong to the cleroid assemblage of families and series, attaching itself to the cleroid family Melyridae (p. 55), but there are on the other hand some reasons for considering the possibility that it might be related to the Cantharoidea.

The third distinct polyphagous larval type that is more primitive than the byrrhoid type and shows closer affinity with the staphylinoid leptinid association is found as mentioned in the series Cucujoida, notably in the families Lathridiidae (p. 33), Derodontidae (p. 33), Silvanidae (p. 34), and Endomychidae (p. 38). Most of the cucujoid families are plainly derived from this type; a few, however, not so plainly, such as the larvae of the family Oedemeridae (p. 40), and the whole tenebrionid association (p. 42⁵⁴⁻⁵⁶), which only indirectly can be traced to the primitive cucujoid larvae through rather advanced cucujoid types like the larvae of the Colydiidae or the Melandryidae.

LARVAL FORMS OF COLEOPTERA

SUBORDERS

The systematic characters defining the larvae of the three sub-orders, whose relative phylogenetic positions now have been discussed, are as follows:

- A. *Archostemata*. Legs six-jointed with distinct tarsus and one or two distinct claws;³ always a mandible possessing a strong molar part, and with hypopharyngeal and paragnathal structures fused with prementum into a strong, hard unit.
- B. *Adephaga*. Legs six-jointed with a well defined tarsal joint and one or two distinct, movable claws;⁴ mandible lacking a molar part; hypopharynx never united with prementum into a strong, hard unit.
- C. *Polyphaga*. Legs five-jointed, the tarsal joint fused with a single claw into a tarsungulus; or less than five-jointed; or no legs present.⁵

³ Except in the instars of *Micromalthus*, which are legless or have three-jointed legs.

⁴ All, or some, of the larval instars of the carabid species *Brachinus janthinipennis* Dej. and *Lebia scapularis* Dej. are adapted to an ectoparasitic life to the extent that it is impossible to place them systematically by a mere examination of the body structures. In the series Paussoidea (p. 24), of which, however, only the last larval instar is known, the legs are three-jointed, but this myrmecophilous larva can be recognized by the unique development of the eighth abdominal segment into a large, terminal, glandular disk. Tibia and tarsus fused in a few cicindelid genera (p. 18).

⁵ Several larvae as the staphylinid genera *Philonthus* and *Bledius*, the first instar of the staphylinid species *Aleochara bilineata* Gyllenhal, *Euplectus*, some genera of Histeridae, and the cerambycid genus *Nothorhina* have the tarsungulus divided by a faint suture into a proximal and distal portion which possibly correspond respectively to tarsus and claw. In several of the Bostrichoidea, particularly in *Ptilineurus marmoratus* Reitter, the tarsungulus has not the usual character of a claw but of a long, pointed, upward curved joint carrying many, strong, spinelike setae, the tarsal portion of the tarsungulus here being predominant.

LARVAL FORMS OF COLEOPTERA

SERIES OR SUPERFAMILIES

The *Archostemata* includes one family series: A, Cupesoidea.

The *Adephaga* includes three family series: B, Caraboidea; C, Gyrinoidea; and D, Paussoidea.

The *Polyphaga* includes eighteen family series: E, Staphylinoidea; F, Hydrophiloidea; G, Cuenjoidea; H, Byrrhoidea; I, Dasilloidea; J, Dryopoidea; K, Cantharoidea; L, Elateroidea; M, Scarabaeoidea; N, Cleroidea; O, Meloidea; P, Mordelloidea; Q, Cerambycoidea; R, Bostrichoidea; S, Chrysomeloidea; T, Platystomoidea; U, Curenlionoidea; and V, Lymexyloidea.

The sequence in which the different family series have been catalogued above and will be treated in the subsequent parts of the paper, except in the key to the series immediately following, intimates a natural arrangement of the series according to the presumed relationship of their larval types (pl. 125).

KEY TO SERIES

1. Leg six-jointed with tarsus distinct and one or two distinct, movable claws present⁶ 2
Leg either five-jointed with tarsus and claw fused into a single, claw-shaped, terminal tarsungular joint, or less than five-jointed, or vestigial, or absent⁷ 4
2. Mandible with molar structure; hypopharyngeal sclerome fused with prementum and ligula into a strongly chitinized unit *Cupesoidea* (p. 16)
Mandible of the grasping type without molar structure, hypopharyngeal region membranous and not fused with prementum and ligula 3
3. Cardo of normal moderate size or small; prementum having stipites labii fused at least proximally. (Tenth abdominal segment usually not armed with large hooks; spiracles usually present) *Caraboidea* (p. 16)
Cardo very large; prementum having stipites labii completely separated. (Tenth abdominal segment armed with four long hooks; spiracles absent; lateral gills present; mandibles perforate) *Gyrinoidea* (p. 24)

⁶ Except in the instars of *Micromalthus* which are legless or have three-jointed legs.

⁷ For further discussion and information see: Snodgrass, R. E., Morphology and Mechanism of the Insect. Smithsonian Miscellaneous Collections, vol. 80, no. 1, 1927, pp. 93-98.

LARVAL FORMS OF COLEOPTERA

4. Eighth abdominal segment glandular, discoidal, and terminal.
 (Ninth and tenth abdominal segments minute, leg three-jointed) *Paussoidae* (p. 24)
- Eighth abdominal segment not glandular and not discoidal 5
5. Urogomphi jointed,^s individually movable. (Often retracted into a terminal breathing pocket in eighth abdominal segment in the Hydrophilidae) 6
- Urogomphi solid or absent 7
6. Maxillary palpiger as a rule closely connected with stipes, not often carrying a finger-shaped galea; spiracles annular.
Staphylinoidea (p. 25)
- Maxillary palpiger free and joint-like, usually carrying a finger-shaped galea; spiracles biforous *Hydrophiloidea* (p. 31)
7. Hypermetamorphosis present; mandible without molar part; maxillary mala short, thick, almost vestigial; gular area present; spiracles annuliform and often large; urogomphi absent⁹ *Meloidea* (p. 58)
- No hypermetamorphosis;¹⁰ different combination of the five mentioned structural characters 8
8. Larva with mandible bearing an accessory ventral condyle and with either a free galea well separated from a distinct lacinia or with cribriiform spiracles, or with both of these characters¹¹ 9
- Larva with a different combination of the characters. (A mandible with an accessory ventral condyle never occurring together with either a free galea or actually cribriiform spiracles) 10

^s Absent in some Pselaphidae, Scydmaenidae, termitophilous Histeridae, and the later instars of parasitic Staphylinidae.

⁹ First larval instar, often named triungulin, triungulinid, or triunguloid, has frequently a pair of setae at the end of the body, and in one subfamily is the eighth abdominal pair of spiracles placed on projecting hooks or warts; the legs have a single, frequently spatulate claw which is provided with one or two setae at the base or at the middle, these setae so large and strong in many genera that they appear as extra claws and for a long time were considered as such; hence the name "triungulinus." Apparently three-clawed legs have occasionally been found in larvae of other series, for instance, in an undetermined lampyrid larva.

¹⁰ *Drilus* has polymorphic metamorphosis and some members of the family Cantharidae have, according to Verhoeff, foetometamorphosis, that is, two free embryonic instars preceding the first larval instar.

¹¹ Accessory ventral condyle absent in the family Passalidae which, however, is readily distinguished by possessing atrophied metathoracic legs (pl. 87).

LARVAL FORMS OF COLEOPTERA

9. Median epieranal suture present; tenth abdominal segment well developed, usually about as large or larger than the well-developed ninth abdominal segment, sometimes fused with it dorsally, when shorter than ninth provided with a pair of large anal pads; spiracles cibiform¹² and all lateral.
- Scarabaeoidea (p. 51)
- Median epieranal suture absent, frons reaching to the occipital foramen; tenth abdominal segment much smaller than the well-developed ninth and always without anal pads, or both ninth and tenth vestigial; spiracles either cibiform and all lateral, or not cibiform and the eighth abdominal pair terminal.
- Dascilloidea (p. 43)
10. Gular region or median gular suture present or absent; when absent, with mandibles having mola or prostheca or extraordinary structures¹³ except a pseudomola 11
- Gular region or gular suture absent; subfacial region of head and ventral region of prothorax contiguous; mandible with pseudomola or with no mola, except in Platystomoidea and Lymexyloidea. (Cardo never completely absent and never distinctly exceeding stipes in size; mala when divided having a lobe-shaped galea; paired urogomphi usually absent) 19
11. Maxillary articulating area either large or indistinct; when indistinct, mandible with mola, except in Catogenidae, Epilachninae and Lamiinae¹⁴ 12
- Maxillary articulating area absent, or very small, or concealed by mentum, not large and cushioned; mandible without molar part 13
12. Maxillary mala divided into a well-developed lacinia and a finger-shaped, one- or two-jointed galea; mandible without a distinct molar part but with a longitudinal series of hairs at the base. (Hypopharynx membranous). Byrrhoidea (p. 43)

¹² Except in some species of *Trox* in which the spiracles are biforous (pl. 87).

¹³ The gular region is completely absent in the cerambycoid subfamily Disteniinae having simple mandibles without mola, in some genera of Lampyridae with perforate mandibles, of Phalacridae without cardo, of Byrrhidae with mala divided into a jointed, finger-shaped galea and prominent lacinia, and in a few others.

¹⁴ The maxillary articulating area is indistinct in some Nitidulidae, Laemophloeidae, Smicripidae, and Lamiinae through fusion with or loss of cardo (pls. 31, 35-38). In some Phalacridae and in the Catogenidae the cardines, the maxillary articulating areas, the submentum, and the gular area are fused more or less completely into one large subfacial membranous region between the diverging hypostomal rods (pl. 33, 34).

LARVAL FORMS OF COLEOPTERA

- Mala simple, or division either indicated by distal notch or present with lobelike galea; mandible with or without a molar part but without a longitudinal series of hairs at the base. (Hypopharynx membranous or with a sclerome) 18
13. Either with exposed gills below the entire abdomen, or with movable operculum usually covering retractile gills at the end of the body, or with mamillaeform appendices from the tenth abdominal segment;¹⁵ mandible never perforate or deeply cleft. (Usually with one large ocellus on each side and without true urogomphi).
- Dryopoidea* (p. 44)
- Gills or anal appendices usually absent; in larvae where present, mandibles either perforate or deeply cleft longitudinally 14
14. Ninth abdominal segment operculate, vertical, and terminal. (Spiracles biforous; body cylindrical and strongly chitinized; mental-submental area distinctly triangular.)
- Elateroidea-Rhipiceridae* (p. 49)
- Ninth abdominal segment otherwise 15
15. Spiracles cribiform; tenth abdominal segment terminal; prothorax large and more or less depressed, usually covered with a plate both dorsally and ventrally.
- Elateroidea-Buprestidae* (p. 49)
- Spiracles, tenth abdominal segment, and prothorax otherwise 16
16. Labrum present *Cleroidea* (p. 55)
Labrum absent or included in nasale. (In Throscidae and Melasidae, head capsule or mouthparts very much reduced or abnormal; prothorax provided ventrally, or both dorsally and ventrally, with pairs of rod-shaped scleromes (pl. 81)) 17
17. Frontal sutures present, except in Throscidae and Melasidae in which head capsule and mouthparts are reduced or very much specialized. (Mandible of the biting labidomorphic type; head capsule with deep subfacial sinus for reception of ventral mouthparts) *Elateroidea proper* (p. 50⁷⁻¹²)
Frontal sutures absent, except in Brachyptectridae and Lamphydidae; both with piercing mandibles. (Mandible of the biting labidomorphic type, or of the subulate type adapted for piercing and sucking; subfacial sinus present or absent¹⁶)
- Cantharoidea* (p. 46)

¹⁵ *Euryopogon*, a type intermediate between the Dryopoidea and the elateroid family Cebriionidae, has no gills or appendices (pl. 69).

¹⁶ Sometimes with pseudoocribiform spirales (pl. 78).

LARVAL FORMS OF COLEOPTERA

18. Ventral mouthparts retracted.¹⁷ (Mandibular molar part usually present) *Cucujoidae* (p. 33) and section 23 (p. 15)
 Ventral mouthparts protracted. (Head capsule ventrally with a broad transverse bridge formed completely or mainly by the large hypostomata; mandible without molar part, often of the gouge-shaped coelate type; legs short or absent.)
Cerambycoidea (p. 60)
19. Hypopharyngeal sclerome absent; mandible without a real molar structure 20
 Hypopharyngeal sclerome present; mandible of the mastieomorphic type with veritable molar structure. (Mentum and submentum well separated; head nutant) 23
20. Ninth abdominal tergum armed with a pair of urogomphi or an unpaired spine. (Tenth abdominal segment without a pair of large lobes separated by median longitudinal groove; legs short, soft, but jointed; terminal joint not claw-shaped; frons short and transverse) *Mordelloidea* (p. 60)
 Ninth abdominal tergum without a pair of urogomphi or an unpaired spine¹⁸ 21
21. Tenth abdominal segment in front of anus provided with a pair of eushioned and adjacent lobes separated by a median, longitudinal groove often marked at the anterior end by a small, transverse sclerome. (Frons indistinct, short, and transverse; frontal sutures faint or absent; epieranial suture present and long, or absent through complete fusion of epicranial halves; mentum laterally free and separated from submentum, except in *Caenocara*; legs four- or five-jointed, usually with rather long, setose, distally pointed, and hard tarsungulus, except in *Cacnucara* where legs are vestigial, two-jointed, and soft) (pl. 101) *Bostrichoidea* (p. 62)
 Tenth abdominal segment in front of anus without a pair of soft, oval lobes separated by a longitudinal groove 22
22. Hypopharyngeal bracon absent. (Frons usually distinct with converging frontal sutures; usually with distinct, four- or

¹⁷ In some forms, as Phalacridae, Laemophloeidae, and possibly Catogenidae, the ventral mouthparts are apparently protracted as a result of elimination of cardines, or fusion of cardines, submentum, and gular area into a large common subfacial region (pls. 31, 32-34).

¹⁸ In exception, paired urogomphi are present in the first larval instar of *Lyctus*, and an unpaired terminal spine is found on the ninth abdominal segment of the first instar of the *Scobicia* larva, but both of the larvae possess in front of the anus a pair of adjacent lobes separated by a longitudinal groove (pls. 101, 102).

LARVAL FORMS OF COLEOPTERA

five-jointed legs with a tarsungular last joint;¹⁹ mentum either free or joined with maxillary stipites; mala often separated into a galea and a lacinia hidden below the galea.)

Chrysomeloidea (p. 63) and *Disteniinae*

Hypopharyngeal bracon present. (Without jointed legs, except in Brenthidae where they are vestigial; mentum connected completely with maxillary stipites, except in Brenthidae; mala simple) *Cuculionoidea* (p. 66)

23. Legs vestigial, without pointed, tarsungular joint, or absent; maxillary mala divided into a lacinia terminating with a thorn, and a galea; body curved, fleshy, and with dorsal, transverse plicae; tenth abdominal segment small, in continuation of ninth *Platystomoidea* (p. 66)

Legs normal, with strong tarsungulus; maxillary mala with only terminal indentation indicating a division into lacinia and galea; body elongate cylindrical, covered with tergal shields; tenth abdominal segment well-developed, asperate, and placed below base of large, chitinized ninth segment.

*Lymexyloidea*²⁰ (p. 67)

¹⁹ Legs are weak or vestigial without a tarsungular joint in the older larvae of Bruchidae and absent in many of the leaf-mining larvae.

²⁰ The systematic position of this series is uncertain. Its larval form approaches in important characters the deviating larvae of the two eucujoid families Oedemeridae and Calopidae, but also greatly resembles the larval form of the ancient suborder Archostemata.

LARVAL FORMS OF COLEOPTERA

FAMILIES, SUBFAMILIES, AND OCCASIONALLY
TRIBES

In the taxonomic arrangement of the larvae, each series includes usually a greater or smaller number of families, subfamilies, and minor subdivisions. In proper order, keys to the families, subfamilies, and occasionally tribes of each of the series listed on page 10 are given below.

A. CUPESOIDEA

KEY TO FAMILIES

1. Ninth abdominal segment extended terminally into a single, conical, straight process, ventrally with a simple, transverse, narrow sternal plate; leg short, conical; tarsus carrying one bifurcate claw with subequal tips. (Polymorphic larval metamorphosis lacking) *Cupesidae* (pl. 1 A-G)
Ninth abdominal segment with terminal process bent downward and directed toward a similar but upward bent process from the sternal plate; leg (in instar in which fully developed) provided with a long, slender tarsus carrying two claws of equal length. (Polymorphic larval metamorphosis present with partly paedogenetic cycle of larval generations.)²¹ *Micromalthidae* (pl. 2 A-J)

B. CARABOIDEA

KEY TO FAMILIES

1. Labial palpi latent; prementum and ligual fused into an unpaired anteriorly bilobed piece. (Retracted ventral mouth-parts; one claw.)^{22a} *Rhysodidae* (pl. 3 A-J)
Labial palpi distinct and jointed 2
2. Ninth abdominal segment present; eighth abdominal segment never terminal. (One or two claws) 3
Ninth abdominal segment rudimentary; eighth long, conical, appearing as the terminal segment of the body. (Two claws) 7
3. Tenth abdominal segment developed as a pygopod for locomotory purpose 4
Tenth abdominal segment not developed as a pygopod 6

²¹ Barber, H. S., Proc. Biol. Soc. Wash., vol. 26, 1913, pp. 185-190.

^{22a} Peyerimhoff, P. de, Rev. d'Ent. vol. 22, 1903, pp. 80-84, one plate.

LARVAL FORMS OF COLEOPTERA

4. Two or three pairs of hooks present on tergum of fifth abdominal segment *Cicindelidae*^{22b} (pl. 4 A-E)
No hooks on fifth abdominal tergum 5
5. Terminal setae of tarsus much shorter than claws; retinaculum single or absent *Carabidae*²³ (pl. 4 F-I)
Terminal setae of tarsus much longer than claws; retinaculum bicuspitate *Omophronidae* (pl. 5 A-E)
6. Thoracic and abdominal spiracles present, biforous, and all lateral; branchial prolongations absent; ninth and tenth abdominal segments separate; tenth abdominal segment long, bifurcate, and attenuate *Halipidae-Haliplinae* (pl. 5 F-H)
Spiracles all absent; branchial prolongations present; ninth and tenth abdominal segments fused into a bifurcate, terminal segment *Halipidae-Peltodytinae*
7. Head nutant; mandible falcate and simple; eighth abdominal spiracle absent. (Gills present below anterior part of body.) *Hygrobiidae (Hygrobia)* (pl. 5 I, J, M)
Head porrect; mandible not simple; eighth abdominal spiracle terminal. (Gills rarely present) 8
8. Mandible with distinct retinaculum, inner margin neither sulcate nor tubular; legs fossorial *Noteridae (Noterus, Hydrocanthus, and Canthydrus)* (pl. 5 K, L, N-P)
Mandible without distinct retinaculum, inner margin either sulcate or tubular; legs ambulatory or natatory 9
9. Prothoracic presternum large and subquadrate; gula²⁴ present, subquadrate or triangular; gular suture double or anteriorly bifurcate *Dytiscidae*²⁵ (pl. 6 A-H)
Prothoracic presternum transverse, narrow, and band-shaped; gula absent; gular suture median and simple. *Amphizoidae* (pl. 7 A-H)

B.I. CICINDELIDAE

KEY TO MAIN TYPES OF LARVAE

1. Each of the paired protuberances on fifth abdominal segment with two hooks 2

^{22b} Key to the main types of cicindelid larvae on pages 17-18.

²³ Key to subfamilies of Carabidae on pages 18-23.

²⁴ The plate or area which appears as the gula may be a morphologically different structure, namely, a pair of medianly fused pieces separated from the gular margin of the epicranium. However, for practical purposes, it is referred to as the gula.

²⁵ Key to subfamilies of Dytiscidae on pages 23-24.

LARVAL FORMS OF COLEOPTERA

- Each with three hooks 4
 2. Exterior hook falcate and outwardly concave; basal joint of labial palpus with two or three spines.

Cicindelini (*Cicindela*)

- Exterior hook straight or slightly concave toward the middle line; basal joint of labial palpus without spines 3
 3. Dorsal pair of ocelli subequal in size

Tetrachini (*Tetracha*)

- Posterior one of dorsal ocelli decidedly larger than anterior.

Amblycheilini (*Amblychela*)
(pl. 4 B, D)

4. Exterior hook much smaller than the other two. (Tibia and tarsus small but separate) *Omini* (*Omus*)
 All three hooks of about the same size. (Tibia and tarsus separate (*Therates*?), or fused)

Collyrini (*Collyris*, *Ctenostoma*, and *Therates* (?))
(pl. 4 A)

B.II. CARABIDAE

Out of the nineteen subfamilies into which the Carabidae have been divided here according to the characters of the larvae, a single one, the Lebiinae, may not be natural. The evidence of a close relationship between the genera which have been included in it is not strong and, considered as a group, its affinities to other subfamilies, particularly to the Dromiinae, can hardly be traced. Furthermore, because of extreme adaptation to an ectoparasitic life in all or some of the larval instars, it is not always possible even to recognize the larvae of some of its species as carabid larvae. In the following key the main character common to the genera of the Lebiinae appears rather insignificant but it sets the subfamily off from all other carabid larvae. Two of the remaining subfamilies, namely, the Dromiinae and the Loricerinae, occupy an isolated position, but the rest intergrades either with one or with several of the other subfamilies. The Dromiinae is in itself a homogeneous and natural group, and the larval form of the subfamily Loricerinae, represented by a single genus only, is very characteristic and strikingly different from other carabid larvae. The larvae of the Odacanthinae show no close relationship to the larvae of the two other "Truncatipennes", the Lebiinae and the Dromiinae, but they approach the Nebriinae. The Driftinae are closely related to the Nebriinae which are rather distant from the Carabinae, according to their larvae. The Cyprininae are closely related both

LARVAL FORMS OF COLEOPTERA

to the Carabinae and to the Chlaeniinae, and between this latter subfamily and the Licininae is an unmistakable affinity. The Bembidiinae, as limited here according to the larvae, represent a natural and well defined subfamily, but the Sphodrinae, Broscinae, and Dyschiriinae, all of which have but one claw on each tarsus like the Bembidiinae, come near to this group. Regardless of a significant lack of similarity with the whole bembidiine association in the number of claws, the Scaritinae may join it, and the Elaphrinae which like the Scaritinae have two claws on each tarsus, are unquestionably related to this latter subfamily. Another association of subfamilies is formed by the Pterostichinae, Amarinæ, and Harpalinae. Connected with this group is the subfamily Patrobinae, which in the larval stage has no connection whatsoever with the Bembidiinae but is difficult to separate from the Pterostichinae. The larvae of the genera *Glyptus* from Africa (pl. 4 I) and *Orthogonius* from India and Africa are termitophilous, blind, with a more or less bottle-shaped, fleshy, soft-skinned body, short legs with but one claw, and no urogomphi. According to the imagoes, their systematic position is with the Amarinæ and Harpalinae.

KEY TO SUBFAMILIES

1. Ligula almost absent and entirely without setae. (Polymorphic metamorphosis; body often degraded because of parasitism)
Lebiinae (*Lebia*, *Brachinus*, and possibly *Pheropsophus*)²⁶ 2
2. Ligula with setae 2
2. Tenth abdominal segment with two protrusile prominences carrying a series of sensorial hooks; with a single exception, claws having a round or tooth-shaped enlargement at base.
Dromiinae (*Dromius*, *Demetrias*, *Euproctus*, *Calleida*, *Philophuga*, *Plotochionus*, *Cymindis*, and *Onota*)

²⁶ *Brachinus janthinipennis* Dejean is ectoparasitic in all larval stages on the pupa of *Dineutes americanus* Say (= *assimilis* Kirby) and pupates inside the mud cocoon of its host (Dimmock, G., and Knab, F., Springfield Museum of Natural History, Bul. 1, 1904). *Lebia scapularis* Fourcroy is ectoparasitic on the larva and pupa of *Galerucella luteola* Müller; while feeding, the parasite is inside a sort of capsule (Silvestri, F., Redia, vol. 2, 1904). *Lebia chlorocephala* Hoffman is not parasitic (Rosenberg, E., Entom. Medd., ser. 2, vol. 2, 1903—Larvae of Lebiini and Odacanthini). *Pheropsophus hispanicus* Dejean is probably not parasitic (Emden, F. von, Supplementa Entomologica, no. 8, 1919).

LARVAL FORMS OF COLEOPTERA

- Tenth segment with no sensorial hooks; claws normal 3
3. Mandible falcate, at least three times as long as wide at base
 (Retinaculum placed at base or in the middle of the inner
 edge) 4
- Mandible robust, about twice as long as wide at base, or
 shorter. (Retinaculum never placed at base; each leg often
 with claws of different sizes) 19
4. Mandible multiserrate in front of retinaculum; nasale not pro-
 jecting but armed with a transverse series of several sharp
 teeth of the same size; two claws of equal size; urogomphi
 immovable *Odacanthinae* (*Odacantha*, *Lep-
 totrachelus*, and *Casnonia*
 (?))
- Combination of the four characters different 5
5. Mandible not serrate in front of retinaculum and without
 groove for antenna; antenna inserted outside of mandible;
 urogomphi movable and long; head round and usually large;
 collum constricted and narrow (except in *Pelophila*) 6
- Different combination of the characters 7
6. Prementum with lateral setae. (Coxa of front leg with inner
 margin of a groove for reception of femur armed with long
 spines; urogomphi multijointed)
- Driptinae* (*Galerita*)
- Prementum without lateral setae. (Urogomphi not jointed,
 finely nodose) *Nebriinae* (*Notiophilus*, *Pelo-
 phila*, *Nebria*, and *Leistus*)
7. Dorsal shield of ninth abdominal segment very small; ligula
 broadly rounded and multisetose; mandible with distal part
 beset with appendices; retinaculum serrate; inner corner of
 mandible receding at base. (Stipes large, swollen; palpus
 shorter than galea) *Loricervinae* (*Loricera*)
- Dorsal shield of ninth abdominal segment distinct; ligula with
 a pair of setae; mandible without appendices and with inner
 corner projecting 8
8. Urogomphi fixed, short, strong, and pointed; prementum with-
 out lateral setae; stipes maxillaris subquadrate, depressed 9
- Urogomphi different; prementum with lateral setae; stipes dif-
 ferent 10
9. Retinaculum with posterior margin simple; urogomphi antler-
 like in mature larvae; labial palpus with apieal joint simple
 and ovate, or terminally cleft. (Ligula distinct in *Calosoma*,
 minute in most species of *Carabus*)
- Carabinae* (*Calosoma*, *Carabus*,
Damaster, and *Procrustes*)

LARVAL FORMS OF COLEOPTERA

Retinaculum with posterior margin serrate; urogomphi conical and simple; labial palpus with apical joint securiform. (Head small, body broad and oval)

Cychrinae (*Cychrus*, *Maronetes*, and *Sphaeroderus*)

- | | | |
|-----|--|----|
| 10. | Two claws of equal size | 11 |
| | One claw | 13 |
| 11. | Collum indistinct; epicranial suture absent or indistinct; mandible, except in <i>Rembus</i> , with serrations, crenulations, or with a few denticulations at least on retinaculum and often also on inner edge in front of retinaculum. (Urogomphi often of unusual shape; distal joint of labial palpus rather thick and conical | 12 |
| | Collum distinct and broad; epicranial suture distinct; retinaculum, and usually the whole inner edge of mandible, entire..... | 16 |
| 12. | Antenna not twice as long as mandible. (Urogomphi either thin and stiff with a few seta-bearing tubercles, or very long, rolled up like a spring, and divided into a large number of minute pseudojoints as in <i>Chlaenius prasinus</i> Dejean and other species of <i>Chlaenius</i>) | |

Chlaeniinae (*Oodes* and *Chlaenius*)

Antenna at least twice as long as mandible. (Urogomphi either movable, long, straight, and pubescent as in *Panagaeus*, or immovable, slender, curved toward each other, and pubescent as in *Dicaelus*, or, immovable, nodose, and with a number of long setae as in several genera)

Licininae (*Rembus*, *Dicaelus*, *Licinus*, *Badister*, and *Panagaeus*)²⁷

13. Galea with proximal joint shorter than, or as long as, the distal one. (Ocelli usually six on each side; in *Trechus*, only three, the two anterior coalescent; in *Anophthalmus*, none.)

Bembidiinae (*Asaphidion*, *Bembidion*, *Cillenus*, *Tachys*, *Tachyta*, *Anophthalmus*, and *Trechus*)²⁸

Galea with proximal joint longer than the distal one 14

²⁷ *Panagaeus* has been given many different places in the classification of the imagines, for instance, close to the *Chlaeniinae* or near the *Bembidiinae*, but according to the larva its systematic position is in the *Licininae*.

²⁸ *Anophthalmus* and *Trechus*, according to the larvae, definitely belong in this subfamily and have no connection with the larva of *Patrobus* which, as mentioned above, is very similar to *Pterostichus*.

LARVAL FORMS OF COLEOPTERA

14. Lacinia present. (Ocelli absent; urogomphi jointed, with basal joint very long, the five distal joints small.)
*Sphodrinae (Sphodrus)*²⁹ 15
- Lacinia absent 15
15. Meso- and metathorax convex laterally; urogomphi much longer than tenth segment, terete, and nodose. (Galea with the proximal joint twice as large as the distal; six ocelli.)
Broscinae (Broscus)
 Meso- and metathorax subparallel laterally; urogomphi as long as or shorter than tenth segment, rather flat and membranous beneath, either very short, almost triangular, and distant at base, in *Dyschirius*, or fairly long, with parallel sides, and united at base, in *Clivina*. (Six ocelli or none.)
Dyschiriinae (Dyschirius and Clivina)
16. Legs fossorial; body with subparallel sides; prothoracic spiraele very large, first abdominal spiracle large, the rest of normal size. (Sternal sclerites of abdomen closely adjacent; either six ocelli or none; urogomphi either smooth and curved toward each other, in *Pasimachus*, or nodose and straight, in *Scarites*) *Scaritinae (Scarites and Pasimachus)*
 Legs ambulatory or rassorial; body fusiform; prothoracic spiracles of normal size. (Six ocelli) 17
17. Urogomphi either with short, setose ramuli, in *Elaphrus*, or thick, cylindrical, and beset with numerous setae, in *Blethisa*; four anal prominences. (Nasale extended into a short horn; with or without lacinia.)
Elaphrinae (Elaphrus and Blethisa)
 Urogomphi terete, nodose or with several setae; two or no anal prominences 18
18. Penicillus absent; lacinia absent; claws slender and not strong; setae of femora fine *Patrobinac (Patrobus)*³⁰
 Penicillus present; lacinia present or at least represented by a strong seta; claws of normal strength; setae of femora moderately strong. (Anterior margin of nasale varying much according to genus; six ocelli, except in the blind *Sphodrop-*

²⁹ This subfamily differs considerably from the Pterostichinae in which, according to the characters of the imagines, its only genus, *Sphodrus*, has been placed between *Pterostichus* and *Laemostenus*, but it approaches, together with the Broscinae, the great and well-defined bembidiine association.

³⁰ See explanatory remarks on page 19.

LARVAL FORMS OF COLEOPTERA

- sis* from European caves; urogomphi short, terete, and curved toward each other in *Evarthrus*, in the other genera long and multinodose) *Pterostichinae* (Genera as placed in Leng's Catalogue in tribes *Pterostichini* and *Platynini*) (pl. 4 F-H)
19. Each leg with two claws of equal length; stipes stout and more or less distinctly divided into a proxistipes and a dististipes of about the same size; lacinia with moderately strong, lateral or terminal seta. (Anterior margin of nasale varying much according to genus, in *Zabrus* produced into two conical teeth; retinaculum very small; urogomphi solid, nodose, usually of moderate length, short in *Zabrus* and *Percosia*.)
Amarinae (*Zabrus* and the genera placed by Leng in *Amarini*)
- Each leg with two claws of different length; stipes normal, rather slender; lacinia with very strong, spinelike, terminal seta. (Anterior margin of nasale varying much according to genus, but never produced into a pair of strong, conical teeth; retinaculum well-developed; inner edge of mandible in front of retinaculum either entire, serrate, or with one to several teeth; urogomphi usually of moderate length, short in a few genera as *Cratacanthus* in which the pygopod is exceptionally short and thick; trochanter with one or two rows of spines on each side) *Harpalinae* (genera as placed by Leng in his tribe *Harpalini*)

B.III. DYTISCIDAE

KEY TO SUBFAMILIES

1. Head with anterior, distally notched prolongation; mandible turned upward with apex fitting into the notch of the prolongation; maxillary palpus three-jointed
Hydroporinae (*Hydroporus*, etc.) (pl. 6 B-D, G)
- Head without anterior prolongation; mandibles directed forward; maxillary palpus four-jointed or more 2
2. Maxillary stipes broad, suboval, with one or two strong hooks on inner margin 3
- Maxillary stipes slender and long, no hooks on inner margin .. 5
3. Seventh and eighth abdominal segments laterally without series of swimming hairs; ligula absent.
Colymbetinae (*Agabus*, *Ilybius*, *Colymbetes*, *Rhantus*, and also *Laccophilus*)

LARVAL FORMS OF COLEOPTERA

- Seventh and eighth abdominal segments with swimming hairs;
ligula present 4
4. With a pair of long lateral gills on the six anterior abdominal
segments *Coptotominae* (*Coptotomus*)
No gills *Thermonectinae* (*Acilus*, *Ther-
monectes*, *Graphoderes*, and
Eretes)
5. Head anteriorly without dentation; ligula either absent, or low
and bilobed; urogomphi present
 Dytiscinae (*Hydaticus* and
 Dytiscus) (pl. 6 A, F, II)
Head anteriorly dentate; ligula long; urogomphi absent.
 Cybistrinac

C. GYRINOIDEA

KEY TO FAMILIES AND SUBFAMILIES

1. Head subcircular with collum narrow and distinct; mandible
falcate without retinaculum
 Gyrinidae-Enhydrini (*Dinecu-
tes*) (pl. 6 E, I-M)
Head elongate with collum about as wide as rest of head and
not distinct; mandible with retinaculum 2
2. Nasale without teeth *Gyrinidae-Orectochilini* (*Orec-
tochilus*)
Nasale with two to four teeth in a transverse row.
 Gyrinidae-Gyrinini (*Gyrinus*)

D. PAUSSOIDEA

The Paussoidea approach the Caraboidea, especially the Rhysodidae and the Carabidae, in fundamental characters but apparently also the series Hydrophiloidea. In common with the first of the two series, the Paussoidea possess a normal maxillary palpiger, four-jointed antenna, and annular spiracles. In common with the second of the series, they have a three-jointed maxillary palpus and a single-jointed galea, characters, however, which also occur in the isolated caraboid family Haliplidae. The posterior part of the abdomen is unique as are also the legs which are only three-jointed and are curved upward. However, reduced legs but of a different type are found both in the Caraboidea, for instance, in stages of *Lebia scapularis*, and in the Hydrophiloidea, for instance, in *Sphaeridium*. It is for practical reasons mostly that the series Paussoidea has been established and placed at the end of the

LARVAL FORMS OF COLEOPTERA

Adephaga. This conception, however, is based on the knowledge of the mature larvae of only two genera, namely, *Paussus* (represented by three species) and *Pleuropterus* (one species), and may be altered by the eventual discovery of the earlier instars and of the larvae of the more primitive genera.

FAMILY

The series consists of a single family *Paussidae* (pl. 7 I-M)

E. STAPHYLINOIDEA

The series contains several fairly distinct associations of families or subfamilies. Two of these are outstanding, namely, the leptinid association containing very primitive larvae, and the staphylinine association with greatly mutated and advanced larval types. To the leptinid association belong the Limnebiidae, Leptinidae, Anisotomidae, and Ptiliidae; to the staphylinine association the very specialized subfamilies Staphylininae, Thinopininae, and Paederinae. The four families which constitute the association of primitive larvae have been placed differently in the classification of the imagines: The Limnebiidae, with genera *Limnebius*, *Ochthebius*, and *Hydraena*, were placed in the beginning of the Hydrophiloidea (auct.); the Anisotomidae, with subfamilies Cholevinae (auct.) and Anisotominae (auct.), and the Leptinidae were included in the beginning of the Staphylinoidea (auct.); the Ptiliidae at the end of this latter series. The Hydroscaphidae are closely related to the Limnebiidae.

From the four primitive staphylinoid families are directly derived the Scaphidiidae, the Platypyllidae, and the Silphidae; the latter merely including *Necrophorus*, *Silpha*, and the few other genera usually listed as "Silphini." The entire family Staphylinidae, as here conceived, consists of a complex of many subfamilies linked together into one large unit.

There is a gradual transition from the Oxytelinae, which represents the nearest approach to the Silphidae, into the Paederinae, which is the most specialized group of all the Staphylinidae. The Pselaphidae and Scydmaenidae are here regarded as families branched off from the Staphylinidae much in the same way as the Hydroscaphidae are branched off from the Limnebiidae, and the Platypyllidae from the Silphidae or Scaphidiidae. The larvae of the small families Brathinidae, Clambidae, Clavigeridae, Sphaeridae, and Sphaeritidae are either completely unknown or are at least not present in the United States National Museum. The Histeridae

LARVAL FORMS OF COLEOPTERA

has been included in our Hydrophiloidea (p. 31) and the Corylophidae placed in the Cucujoidea near the Phalacridae (p. 36) and Smieripidae (p. 36). The Micropeplidae is listed in the Staphylinoidea according to an incomplete description by Lubbock (Trans. Ent. Soc. London, 1868, p. 275, one plate) but the larva may not belong in this series at all.

KEY TO FAMILIES AND SUBFAMILIES

- | | |
|---|---|
| 1. Mandible with a, usually large, asperate or tuberculate molar part | 2 |
| Mandible without asperate or tuberculate molar part, usually without molar part | 7 |

Leptinid association:

- | | |
|---|---|
| 2. Tenth abdominal segment provided with a pair of recurved hooks | <i>Limnebiidae</i> (<i>Ochthebius</i> , <i>Hydraena</i> , and <i>Limnebius</i>) (pl. 8 A-L) |
| Tenth abdominal segment without terminal hooks but sometimes with a pair of long setae | 3 |
| 3. Spiracles absent; balloonlike appendices on prothorax, first and eighth abdominal segments; antenna very short and two-jointed | <i>Hydroscaphidae</i> (pl. 9 A-F) |
| Spiracles present; no balloonlike appendices; antenna three-jointed | 4 |
| 4. Apex of mandible multiserrate; urogomphi short, one-jointed. | <i>Ptiliidae</i> (<i>Nossidium</i>) (pl. 10 F-L) |
| Apex of mandible bifid or trifid; urogomphi two-jointed, last joint often multiannulate | 5 |
| 5. Mandible with vestigial retinaculum (r). | |
| <i>Leptinidae</i> (pl. 10 A-E) | |
| Mandible with distinct retinaculum (r), or prostheca (lm), ³¹ or both | 6 |
| 6. Asperities on molar structure covering entire ventral surface, irregularly arranged; paraglossae as long as ligula. | |
| <i>Anisotomidae-Liodinae</i> ³⁷ (pl. 11 A, B) | |
| Asperities on molar structure arranged in fine transverse (often few) rows; paraglossae absent or shorter than ligula. | |
| <i>Anisotomidae - Choleviniae</i> ³⁷ (pl. 11 C-M) | |
| 7. Mala and stipes fused | 8 |
| Mala jointlike, movable | 23 |

³¹ Except in *Aphaobius*, belonging to the Anisotomidae-Choleviniae but very similar to the Leptinidae. (L. Weber, Allg. Ztsch. f. Ent. vol. 7, 1902).

LARVAL FORMS OF COLEOPTERA

Silphid association:

8. Mandible with apex simple, recurved, and bent away from the sagittal plane of the larva. (Ligula rounded and entire.)
Platypyllidae (pl. 12 E-I, K)
 Mandible with apex differently shaped, never recurved 9
9. Galea present; often developed as a small, hairy lobe on top of lacinia. (Ligula bi- or trilobed) 10
 Mala maxillaris simple. (Ligula either deeply bilobed, or entire, or absent)³² 12
10. Lacinia with entire surface asperate; terminal joint of maxillary palpus subulate; ligula trilobed.
Scaphidiidae (pl. 12 A-D, J)
 Lacinia not asperate or only along posterior margin; terminal joint of maxillary palpus not subulate; ligula bilobed 11
11. Dorsal shields small, the abdominal ones quadrispinose; ventral surface whitish and soft
Silphidae-Necrophorinae
 Dorsal shields large, usually laterally produced with posterior angles aeuminate; ventral surface with well sclerotized shields *Silphidae-Silphinae*³⁷ (pl. 13 A-J)
12. Ligula either deeply bilobed anteriorly, or absent; nasale present 22
 Ligula entire anteriorly; labrum distinct, often movable 13

Oxyporine association:

13. Mandible narrowed at the middle, apically bifid and finely mucronate. (Ligula small and quadrate.)
*Staphylinidae-Oxyporinae*³³
 Mandible different 14
14. Ligula broad, anteriorly either rounded, straight, or slightly emarginate 15
 Ligula conical, often transversely bipartite at base 18
15. Mandible with suddenly dilated molarlike base. (Apically with three or four teeth and ocelli several in number) 16
 Mandible with no molarlike base³⁴ 17

³² The mala is crowned in several species of *Bledius* and in *Syntomium* with a hairy, rounded projection which might be interpreted as a vestigial galea, but the ligula is simple and rounded.

³³ The anatomical details of head and body have a primitive character; the systematic relationship to the oxyteline association is rather remote, and the systematic position somewhat isolated.

³⁴ In the aleocharine genera *Leptusa* and *Silusa* the base is somewhat dilated, but the apex is bifid or entire and only one ocellus is present.

LARVAL FORMS OF COLEOPTERA

Oxytelinae association:

16. Larva elongate; anal segment conical, ventrally directed; with four ocelli on each side

*Staphylinidae-Piestinae*³⁵ (*Piestus* and *Lispinus*) (pl. 14 B, C, E, F, H)

Larva ovate, short, body capable of contraction into a globe; anal segment small, short, laminate, posteriorly directed; three ocelli on each side.

Staphylinidae - Syntomiinae (*Syntomium*)³⁶

17. Mandibles apically more or less widened, bifid or trifid, sometimes asymmetrical; number of ocelli on each side, three, one, or none

*Staphylinidae - Oxytelinae*³⁷ (*Bledius* with termitiform body and three ocelli, *Platystethus* and *Aploderus* with dark spots laterally on most segments, *Oxytelus*, *Coprophilus*, and *Trogophloeus*) (pl. 15 D, G, H, L)

Mandibles apically not widened, either slightly forked or entire; with one ocellus

*Staphylinidae-Aleocharinae, part one*³⁷ (*Gyrophaena* with eighth abdominal segment terminally produced into a glandular process, *Mieroglotta*, *Maseochara*, and many other genera) (pls. 14 A, D, G, I and 16 F-I)

18. Ligula simple, conically pointed; one ocellus .

*Staphylinidae-Aleocharinae, part two*³⁷ (*Leptusa* and *Silusa* with mandibles suddenly enlarged at base, *Atheta*, and many other genera).

Ligula transversely bipartite at base; three to six ocelli on each side

19

³⁵ The classification of the Piestinae as a subfamily conforms with the views of many European entomologists, and the larvae are easily recognized, but their subfamily characters are of disputable value. Bernhauer's and Schubert's conception of the group as a mere tribe of the Oxytelinae may prove to be the more satisfactory. It is with great hesitation that the Piestinae are placed here as a subfamily separate from the Oxytelinae.

³⁶ The larva of *Coprophilus* possesses falciform urogomphi shaped like the mandibles of a *Dytiscus* larva. It differs greatly in type from *Syntomium*, and has here been placed in the Oxytelinae.

³⁷ It is a very difficult taxonomic problem to find distinctive characters for the separation of the subfamilies Oxytelinae and Aleo-

LARVAL FORMS OF COLEOPTERA

Omaliine association:

19. Maxillary mala fanglike, smooth, and as long as entire head.
(Three or six ocelli on each side).

Staphylinidae-Proteininae (*Proteinus*
and *Megarthus*)³⁸ (pl. 16 J-M)

Maxillary mala shorter, with hairs. (Four to six ocelli on each side) 20

20. Mandible apically entire. Lacinia with or without pectinate inner edge; (ocelli six or less on each side).

Staphylinidae-Omaliinae (*Anthobium*,
Omalium, *Olophrum*, and other genera) (pl. 17 B, D, F, G)

Mandible bifid. Lacinia with pectinate edge; (ocelli six) 21

21. Body biconvex; head nutant, laterally rounded; mala subtrapezoidal *Staphylinidae-Tachyporinae* (pl. 15 C, E, I-K)

charinae. In the Aleocharinae, the "part two" characterized by the presence of a simple, conical ligula is easily set off, thus causing no difficulties, but "part one" with a broad and rounded ligula isomorphous with the one found in the Oxytelinae is not separable from the latter subfamily by a single definite character as a comparison between the alternatives given in section 17 will show. However, in the general appearance of the larvae of the two subfamilies there is a lack of conformity that warns against any digression from the commonly accepted classification. In many aleocharine larvae, certain characteristic changes or radical adaptations to special biological conditions such as a fungicolous, myrmecophilous, termitophilous, or endoparasitic life make the determination to subfamily or even to series extremely difficult or impossible. The urogomphi, for instance, have disappeared in the myrmecophilous larvae of *Lomechusa*, *Xenodusa*, and *Atemeles*; and in *Aleochara bilineata* Gyllenhal only the first instar is built normally and is free living, but having found and gnawed its way into the puparium of a fly it changes into a very reduced endoparasitic second instar which is followed by a similarly reduced endoparasitic third instar. Other species of *Aleochara*, and *Maseochara valida* LeConte are also known to have endoparasitic larval instars in the puparia of flies or cocoons of sawflies. (See: N. A. Kemner: "Die Lebensweise und die parasitische Entwicklung der echten Aleochariden," Entom. Tidskrift, 1929, pp. 133-170, four plates.)

³⁸ The classification of the Proteininae as a subfamily is questionable. It is characterized by the extraordinary development of the mala, but is closely approached in this and other characters by genera such as *Lathrimaeum* belonging to the Omaliinae. (See important paper by N. A. Kemner concerning the larvae of the Proteininae; Entom. Tidsskrift, 1925, pp. 61-76, two plates.)

LARVAL FORMS OF COLEOPTERA

Body depressed; head porrect, laterally parallel; mala subtriangular *Staphylinidae - Habrocerinae* (*Olisthaerus* and *Habrocerus*)³⁹

Steinine association:

22. Urogomphi long and two-jointed; antenna more than twice as long as head; ligula bilobed; six ocelli on each side.

Staphylinidae-Steninae (pl. 17 A, C, E)

Urogomphi absent or small and immovable; antenna not longer than head; ligula absent; less than six ocelli, sometimes no ocelli 25

Staphylinine association:

23. Legs strong, fossorial; urogomphi one-jointed, thick, sansage-like *Staphylinidae-Thinopininae* (pls. 15 B and 18 A, D, E, G, H-J)

Legs cursorial; urogomphi two- or three-jointed 24

24. Ocelli, four or less on each side.

Staphylinidae-Staphylininae (*Xantholinus* with one ocellus, *Othius* with none, *Quedius* in many species with club-shaped or capitulate setae, *Staphylinus*, *Philonthus*, and other genera.)

Ocelli, five or six *Staphylinidae-Paederinae* (pl. 18 B, C, F)

Pselaphid association:

25. Terga expanded laterally, body oval 26
Terga not expanded. (Antenna not club-shaped.)

*Pselaphidae*⁴⁰ (*Batrisodes* and *Euplectetus*) (pl. 19 E-J)

26. Tergal shields smooth, with simple hairs; antenna with second joint very large and club-shaped.

*Scydmaenidae*⁴⁰ (*Scydmaenus* and *Eumicrus*) (pls. 16 A-E and 19 A-D)

³⁹ The larvae of *Olisthaerus*, of which two European species are completely described and figured by Saalas (Uunio Saalas p. 69) agree in every character with *Habrocerus* (*schwarzi* Horn) and the two genera constitute together a subfamily that comes close to the staphylinine association having a porrect head and antennae inserted dorsally near the anterior margin of the head. The subfamily also approaches the Piestinae and Oxytelinae, thus forming a remarkable link between the more primitive and the highly transformed and advanced Staphylinidae.

LARVAL FORMS OF COLEOPTERA

Tergal shields tuberculate; with fan shaped hairs.
Micropelidae (?)

F. HYDROPHILOIDEA

This series is not identical with the series named Hydrophiloidea in the classification of the imagines but it is considered expedient to retain the serial name Hydrophiloidea for the present association of families which according to their larvae constitute a homogeneous unit and to which the genus *Hydrophilus* belongs. The Histeridae are included in this series on account of an unquestionable conformity in the development of the fundamental systematic characters in the larvae of the Histeridae and Helophoridae. The Limnebiinae, Hydraeninae, and Hydroscaphidae of the authors belong in the series Staphylinoidea according to the form of their maxillary palpigers and spiracles.

KEY TO FAMILIES AND SUBFAMILIES

1. Nine complete abdominal segments; tenth small. (First to eighth abdominal spiracles lateral and well developed) 2
- Eight complete abdominal segments. (Ninth and tenth reduced; first to seventh abdominal spiracles lateral and small or apparently absent, eighth abdominal spiracle terminal, sometimes poorly developed; usually with a terminal breathing pocket; occasionally with gills) 3
2. Cardo fused with stipes; one ocellus (*Epierus*) or none; coxae small and widely separated. (Tarsus either short and falciform, or long, flexible and terminally filiform; urogomphi of moderate length and usually two-jointed, or short and two-jointed with proximal joints fused at base in *Plegaderus* and *Epierus*, or reduced to a pair of warts. Some termitophilous larvae from British Guiana with rather stiff, digitiform processes on the sides of the body, one pair to each segment) *Histeridae*⁴¹ (pls. 20 A-R and 21 I)
- Cardo distinct; six ocelli; coxae large, approximate. (Tarsus falciform; urogomphi diverging, long, three-jointed, tapering into a thread-shaped end; mandibular penicillus very

⁴⁰ The Pselaphidae and Scydmaenidae are very closely related, differing mainly from each other in the form of the antennae and the size of the abdominal spiracles in proportion to the size of the thoracic spiracles. According to the larvae, the Scydmaenidae may have some connection with the Scaphidiidae, but like the Pselaphidae they approach more closely to staphylinid genera like *Bledius*.

⁴¹ The subfamily Hololeptinae with the genus *Hololepta* as type can not be retained in the classification of the larvae.

LARVAL FORMS OF COLEOPTERA

- short *Helophoridae (Helophorus)* (pl. 21 A, D, E)
3. Head slightly inclined; antenna inserted nearer the lateral margin of the head than is the mandible; ventral mouthparts retracted; gula well developed, quadrangular, and attaining the occipital foramen 4
- Head elevated; antenna inserted farther from the lateral margin of the head than is the mandible; ventral mouthparts protracted; gula reduced to a triangular preregular plate and a single, median, posterior gular suture 5
4. Mandible apically bifid and without molar part; maxillary stipes with strong projecting lacinia; maxillary palpiger with long, conical galea; abdominal segments soft, with short conical gills (?); last three abdominal segments attenuate, not forming a breathing pocket.

Spercheidae (Spercheus) (pl. 21 B, C, F-H)

Mandible apically ending abruptly and with a terminal, short seta, molar part present; stipes with rudimentary lacinia; palpiger without galea; abdominal segments with well-developed plates; last three abdominal segments forming a breathing pocket *Hydrochidae (Hydrochus)* (pl. 22 A, D)

5. Seven pairs of very long gills on sides of abdomen; no breathing pocket. (Ninth and tenth abdominal segments apparently absent) *Hydrophilidae - Berosinae (Berosus)* (pl. 22 B, E)

- Gills (?) of moderate size or absent; with breathing pocket 6
6. Maxillary stipes long and styliform; femora with fringes of long swimming hairs. (Gills (?) present or absent.)

Hydrophilidae - Hydropoliniæ (Hydrous, Hydrophilus, and Tropisternus) (pls. 22 F, G and 23 A)

- Stipes moderately or very broad; femora without fringes of swimming hairs. (Gills absent) 7
7. Ocellar group often large; ocelli equally developed and rather distant. (Legs generally of normal size and visible from above; abdomen more or less tapering posteriorly; nasale often with more than three teeth; nasale and anguli frontales often asymmetrical) *Hydrophilidae-Hydrobiinae* (pls. 22 II-S and 23 B, G, H)

Ocellar group small; ocelli of different size, or closely aggregate. (Legs poorly developed or absent; abdomen often truncate posteriorly; nasale with a single tooth or three small teeth; nasale and anguli frontales symmetrical).

Hydrophilidae-Sphaeridiinae (Chae-
tarthria, Coelostoma=Cyclonotum,
Cercyon, etc.) (pls. 23 C-F, I-P and
24 A-T)

LARVAL FORMS OF COLEOPTERA

G. CUCUJOIDEA

KEY TO FAMILIES AND SUBFAMILIES

1. The back of the mandible either with two long, flagellate setae distally, and the body of the mandible partially fleshy or fully chitinized; or the back of the mandible without long setae distally, and the body of the mandible always fleshy, only with the base, or the tip and the base chitinized. (Maxillary mala entire) *Lathridiidae*,⁴⁹ *major part* (pl. 25 A–J)
The back of the mandible without long, flagellate setae distally, and the body of the mandible completely chitinized 2
 2. Maxillary mala with distinguishable lacinia and galea 3
Maxillary mala entire, sometimes bilobed anteriorly 5
 3. Second antennal joint more than four times as long as the basal joint *Lathridiidae*,⁴⁹ *minor part*
(Eufallia) (pl. 25 K, L)
Second antennal joint subcylindrical, three times, or less, as long as the basal joint 4
 4. Spiracles annular, not on tubes; urogomphi not distinct
*Eucinetidae*⁴² (pl. 26 A–H)
Spiracles biforous, on tubes; urogomphi strong
Derodontidae (pl. 27 A–H)
 5. Mala falciform 6
Mala obtuse, or with inner margin irregularly jagged 14
 6. Spiracles biforous 7
Spiracles annular 11
 7. Spiracles, at least some, borne on tubes; urogomphi terminating abruptly with two or three conical processes. (A paramedian process present in front of each urogomphus) 8
Spiracles not on tubes; urogomphi terminally pointed and simple, or urogomphi absent. (Usually without paramedian processes) 9
 8. Labial palpus one-jointed. (Tergal plates armed with series of chitinous tubercles with a small, fan shaped hair on the top) *Monotomidae*⁴³ (*Europs* and *Hesperobaenus* but not *Smicriips*) (pl. 25 M–U)
Labial palpus two-jointed *Rhizophagidae* (pl. 28 A–G)
 9. Mandible with three apical teeth. (Cutting edge between
- ⁴² Apart from the lack of jointed urogomphi, the larva of the Eucinetidae agrees with the larval form of the leptinid association of the Staphylinoidea. Usually the family is placed as a subfamily of the Dascillidae.
- ⁴³ The genus *Smicriips*, usually placed in the Monotomidae, constitutes a separate family, Smicripidae (p. 36²⁰), near the Phalacridae according to the characters of the larva.

LARVAL FORMS OF COLEOPTERA

- apex and retinaculum entire and incurved; retinaculum short and broad; a fleshy lobe present behind mola; body cylindrical) *Languriidae-Languriinae*⁴⁴ (pl. 28 H-J, L, N) 10
- Mandible with two apical teeth. (Cutting edge between apex and retinaculum with one or many projections; body fusiform) 10
10. Cutting edge of mandible behind the apical teeth with a single rounded projection; retinaculum short and broad. (Urogomphi present) *Languriidae-Cladoxeninae* (pl. 28 K, M, O-Q)
- Cutting edge of mandible behind the apical teeth multiserrate; retinaculum long, slender and brittle. (With or without urogomphi) *Cryptophagidae* (pl. 29 A-U) 12
11. Urogomphi absent. (Ninth abdominal segment small or very small; tenth segment conical and often long) 12
- Urogomphi present 13
12. Antenna with second joint large and elavate; apical joint minute *Silvanidae-Silvaninae*⁴⁵ (pl. 30 A-J)
- Antenna with three well-developed normal segments *Silvanidae - Telephaninae*⁴⁵ (pl. 30 K-O)
13. Tenth abdominal segment long and conical *Cucujidae - Brontinae* (= *Hyliotinae*)⁴⁵ (pl. 31 L) 15
- Tenth abdominal segment short and wart-shaped *Cueujidae-Cueujinae*⁴⁵ (pl. 31 A-F)
14. Mentum with only apex free, or small, or indistinct by fusion with other areas. (Exceptionally, in the Sphindidae, mentum free to base and distinct, but appearing together with a mandible provided with retinaculum and a ninth abdominal segment without urogomphi) 15
- Mentum with more than apex free, often free to base, always well developed and distinct. (Mandible, except in genus *Deretaphrus*, without retinaculum; urogomphi usually present) 35
15. Head swollen laterally, and much broader than thorax; cardo of normal shape and position; maxillary articulating area round and well developed; hypostomal inner margin concave between fossa for mandible and posterior end of cardo *Prostomidae*⁴⁵ (pl. 33 A-H) 16
- Different development of some, or all, of the four characters 16
16. Maxillae appearing protracted in front of the mandibular

⁴⁴ The family Languriidae is usually considered as a subfamily of the Erotylidae. See also footnote⁵¹.

LARVAL FORMS OF COLEOPTERA

articulations by a complete or partial elimination of the cardines	17
Maxillae deeply retracted. (Cardines distinct, or fused with stipites)	22
17. Urogomphi present; terga without glandular openings ("foramina" of Peyerimhoff)	18
Urogomphi absent; terga with paired glandular openings. (Labrum and clypeus fused with frons into a nasale; tarsungulus with a long adhesive hair)	21
18. Eighth abdominal segment distinctly longer than seventh. (Small ninth abdominal segment with comparatively large urogomphi; often developed as a springing apparatus)	
<i>Laemophloeidae⁴⁵</i> (pls. 31 G-K, and 32 H, I, K, L, P, Q)	
Eighth abdominal segment about as long as seventh or shorter	19
19. Larva parasitic and physogastric with slightly chitinized, white head and body. (Mandible without mola)	
<i>Catogenidae⁴⁵</i> (pl. 33 I, J, L, M, O)	
Larva not parasitic and not physogastric, head and body normally chitinized. (Mandible with, or, in single species, without mola)	20

⁴⁵ All of the following families and subfamilies—

- a. Cucujidae-Brontinae (including the genera *Brontes*, *Dedrophagus*, and *Psammoecus*),
- b. Cucujidae-Cucujinae (including the genera *Cucujus*, *Pediacus*, and *Platisus*),
- c. Prostomidae (including the genera *Prostomis* and *Dryocora*),
- d. Laemophloeidae (including the genera *Prostominia*, *Narthecius*, *Lathropus*, *Laemophloeus*, *Dysmerus*, *Hemipeplus*, *Inopeplus*, and *Phloeostichus*), and
- e. Catogenidae (including the genera *Scalidium* and *Catogenus*)— are usually considered as one family, the Cucujidae, together with the genera *Oryzaephilus*, *Silvanus*, *Cathartus*, *Nausibius*, *Coccidotrophus*, *Eunausibius*, and *Telephanus*. These latter genera, according to the characters of the imagines, have lately been recognized by J. W. Wilson as constituting a separate family, the Silvanidae. (The Genitalia and Wing Venation of the Cucujidae and Related Families, Ann. Ent. Soc. Amer., June 1930, vol. 23, pp. 305-358). Doctor Wilson, however, does not find that the genitalia, wing venation, and body characters furnish a basis for a division of the Cucujidae (*sensu* Wilson) into four separate families, Cucujidae, Prostomidae, Laemophloeidae, and Catogenidae, as borne out by the characters of their larvae.

LARVAL FORMS OF COLEOPTERA

20. Apical joint of labial palpus normal; hypostomal rods diverging posteriorly. (Submental-gular plate absent, indistinct, or distinct) *Phalacridae* (pls. 32 A-G, and 33 N, P-T)
 Apical joint of labial palpus minute; hypostomal rods parallel. (Submental-gular plate present and distinct)
*Smicripidae*⁴³ (pl. 32 J, M-O)
21. Body elongate elliptical; all of the setae normal; first to seventh abdominal segments dorsally with large glandular openings (or "foramina"); nasale transverse and subrectangular *Corylophidae - Arthrolipinae*
 (*Arthrolips* and *Orthoperus*)⁴⁶
 (pl. 34 A-C)
 Body broadly elliptical; many of the setae fanlike, or flagellate, or clubshaped covered with spinulae; first and eighth abdominal segments with "foramina"; nasale forming an eye-shadelike structure which covers all of the mouthparts
Corylophidae - Corylophinae
 (*Corylophodes*, *Sericoderus*,
Sacium, *Molamba*)⁴⁶ (pl. 34 D-I)
22. Cardo either comparatively small, narrow, often spindle-shaped, and longitudinally directed, or large, about as long or longer than stipes, triangular, and immovable, without posterior condyle. (Labial palpus one-jointed) 23
 Cardo either of moderate size, subtriangular, much shorter than stipes, and obliquely directed, or large, elongate-trapezoidal, movable, and with a posterior condyle, or fused with stipes to a large, movable structure with a posterior condyle. (Labial palpus one-jointed or two-jointed) 27
23. Cardo comparatively small, narrow and longitudinally directed 24
 Cardo large and triangular 25
24. Mandible with lamellate, usually long, multiserrate projection from inner margin between apex and molar part; maxillary mala with uncus on middle of inner margin; adhesive tarsungular hair absent. (Spiracles biforous; urogomphi present) *Nitidulidae-Nitidulinae* (pl. 35 A-H, J)

Mandible with large, lobe-shaped projection from inner margin between apex and molar part; maxillary mala subeylindrical

⁴⁶ P. de Peyerimhoff, Études sur les larves des coléoptères, II. *Corylophidae*, Ann. Soc. Ent. France, vol. 90, 1921, pp. 99-106, pl. 3.—According to the imagines the family *Corylophidae* is usually placed as an aberrant family in the Silphid association, but the larvae indicate no relationship to this group.

LARVAL FORMS OF COLEOPTERA

- drietal, without uncus on middle of inner margin; adhesive tarsungular hair present and twice as long as tarsungulus itself. (Palpiger large, somewhat jointlike; labrum fused with clypeus; urogomphi reduced to a pair of wart-shaped tubercles) *Nitidulidae - Meligethinae*⁴⁷ (pl. 36 A-I)
25. Urogomphi present, short, broad, flat, and shoe-shaped with tips horizontal and turned toward each other; mala with uncus on middle of inner margin; adhesive tarsungular hair absent. (Mandible without lamellate, multiserrate inner margin between apex and the long, strong molar part; spiracles annular) *Nitidulidae - Prometopinae* (pl. 35 I, K-M)
- Urogomphi absent; mala without uncus; adhesive tarsungular hair present 26
26. Mala well-developed and cylindrical; maxillary palpus three-jointed; cardo not longer than stipes; no projections from eighth and ninth abdominal segments. (Inner margin of mandible behind apex multiserrate but without lamellate, lobe-shaped projection) *Nitidulidae-Cateretinae* (*Brachypterus*, *Amartus* and *Heterostomus*)⁴⁷ (pl. 36 J-P)
- Mala vestigial or absent, maxillary palpus two-jointed; cardo longer than stipes, subtriangular, and separated from stipes by a fine suture, both pieces membranous; eighth and ninth abdominal segments with a pair of conical and membranous projections laterally *Cybocephalidae*⁴⁸ (pl. 37 A-G)
27. Mentum well developed and free to base. (Mandibles symmetrical and with distinct retinaculum; urogomphi absent; spiracles annular; body with only fine and simple setae) *Sphindidae*⁴⁹ (pl. 41 F, H-M)
- Mentum not well developed, often fused with submentum, only free apically 28
28. Mandible with large, multituberculate or multicarinate molar structure; cardo proper distinct and subtriangular. (Body

⁴⁷ K. V. Verhoeff has proposed a new family, the Brachypteridae, including the two subfamilies, the Meligethinae and the Cateretinae, on larval characters. (Beiträge zur Kenntnis der Coleopteren-Larven mit besondere Berücksichtigungen der Clavicornia, Archiv. für Naturgeschichte, vol. 89, A. Heft 1, 1928, pp. 1-109, seven plates).

⁴⁸ The Cybocephalidae are usually considered as a tribe or a subfamily of the Nitidulidae. Larva described and figured by F. Silvestri (Metamorfosi del *Cybocephalus rufifrons* Reitter, Bol. Lab. Zool. Gen. e Agr. R. Senola Super. Agr. Portici, vol. 4, 1910, pp. 221-227; 13 figures referring to the larva).

LARVAL FORMS OF COLEOPTERA

- often with numerous fan-shaped, spinulose, or otherwise uncommonly formed, small hairs; juxta-cardo present) 29
- Mandible without large, multituberculate or multicarinate molar structure 31
- 29. Body cheloniform, similar to body of a scale insect; along the sides with flat projections carrying spinulose setae. (Head not visible from above; distal end of maxillary mala provided with a brush of long, club-shaped hairs)
 - Murmediidae*⁴⁹ (pl. 27 I-L)
 - Body different. (Maxillary mala with or without a terminal brush) 30
- 30. Distal end of maxillary mala with a brush consisting of a few, about four, long, stiff, curved and pointed setae; mandible with distinct apical part *Endomychidae - Mycetaeinae*⁴⁹ (Pl. 39 A-G)
 - Distal end of maxillary mala with a differently shaped, often large brush, or without a brush, or with a brush with few setae but then with a mandible without apical part.
- 31. Mandible with reduced, smooth, and usually condyliform molar (mola like?) structure; distinct hypopharyngeal sclerome present. (With or without cardo; juxtaardo absent; with or without lacinia mandibulae; three ocelli present on each side of head, except in the blind termitophilous larva of *Ortalistes rubidus* Gorham, from Barro Colorado island, Canal Zone, Panama)
 - Coccinellidae-Coccinellinae* (pls. 37 H-L and 38 A-I)

⁴⁹ The larva of the different endomychid genera are remarkably distinct from each other, strongly emphasizing the compound character of the family. On the other hand, the family is closely linked both with the Lathridiidae and the Murmediidae, notably through the endomychid *Rhymbus*. The larva of this genus occupies a remarkable central position, approaching the specialized larvae of the major part of the lathridiid genera in the unique development of their mandibles, the primitive larva of the lathridiid genus *Eufallia* in having an almost separate lacinia and galea, and the Murmediidae in the possession of tufted pleural projections. Through this larva the Endomychidae and all of the families which are closely or more remotely related to them may be traced to primitive ancestors, in reality to near the leptinid association of the Staphylinoidea.

The larva of the Sphindidae, interpolated here before the endomychid association, represents unquestionably a simple, primitive eucujoid type, but its more precise systematic position is rather uncertain. (Compare pp. 109 and 110 in the paper by Peyerimhoff, quoted in footnote number 46).

LARVAL FORMS OF COLEOPTERA

Mandible without molar structure; hypopharyngeal sclerome weak or absent	32
32. Body armed with many long, often branched, setiferous dorsal and lateral processes	33
Body without long setiferous dorsal and lateral processes	34
33. Three ocelli on each side; urogomphi absent; lacinia mandibulae absent	<i>Coccinellidae-Epilachninae</i> (pl. 38 J-N)
Five ocelli on each side; urogomphi well developed, often as long as body; lacinia mandibulae large	<i>Erotylidae</i> ⁵⁰ (pl. 41 A-E, G)
34. Mentum and submentum not fused	<i>Dacnidae</i> ⁵⁰ (pl. 42 A-T)
Mentum and submentum fused. (Prementum, mentum, submentum, and gula with a common, hourglass-shaped plate toward which anterior part of hypostoma sends a bridge as in Staphylinini)	<i>Melandryidae</i> ⁵⁰ (pl. 43 A-Z, AE)
35. Body terminating in a deciduous ovate appendix	<i>Scaptidae</i> ⁵⁰ (pl. 44 A-E)
Body not so	36
36. Mandible with a taillike, hairy appendix or a fleshy, hairy lobe behind the base of mola. (Right and left mandibles only slightly different)	37
Mandible without such appendix or lobe	38
37. Hypopharyngeal sclerome strong and ring-shaped; three large and two or three small ocelli present on each side of the head; appendix of mandible tail-shaped	<i>Byturidae</i> ⁵¹ (pl. 45 A-N)
Hypopharyngeal sclerome small and shaped like a cup on top of a large, slightly chitinized dome; one ocellus present on each side of head; appendix of mandible lobe-shaped	<i>Anthicidae - Euglenidae - Anaspidae</i> ⁵¹ (pls. 46 A-W and 47 A-I)

⁵⁰ From the family Melandryidae are excluded the genera *Eustrophus* and *Penthe* which are placed in the family *Dacnidae*, the genus *Scaptia* which forms a separate family, Scaptidae, and the genus *Synchroa* which also forms a separate family, Synchroidae.

⁵¹ In *Anthicus heroicus* Casey the cup-shaped top of the hypopharynx is very thinly chitinized and is recognized only by careful examination. The genus *Anaspis*, usually considered as belonging to the Mordellidae, can by no character be distinguished from the Anthicidae; neither can the euglenid genus *Hylophilus* according to the larva of *Hylophilus populneus* Panzer which has been reared by E. C. Rosenberg in Denmark. The mandibles of the family

LARVAL FORMS OF COLEOPTERA

38. Abdominal spiracles located in disklike scleromes. (Urogomphi branched, with the inner prong directed toward the sagittal line) *Eurystethidae* (= *Aegialitidae*)
 (pl. 48 A-F)
- Abdominal spiracles not located in disklike scleromes 39
39. Mandible without molar structure. (Larva parasitic and physogastric) *Bothrideridae* (*Deretaphrus* and *Bothrideres*) (pl. 44 F-N)
- Mandible with molar structure 40
40. Larva elongate, cylindrical or subcylindrical, or more fusiform. (Body well chitinized or fleshy; urogomphi present and corniform, or absent) 41
- Larva elongate and strongly depressed with parallel sides. (Body smooth and shining; urogomphi always present and often of very distinctive shape) 49
41. Cardo simple 42
- Cardo divided into two parts 44
42. Hypopharynx only slightly or not chitinized; mandibles symmetrical. (Mola of mandible depressed with a ventral grinding surface; presternum of prothorax subtriangular; often with a small pit between bases of urogomphi)
Colydiidae (*Colydiini*, *Synchitini* and, probably, *Monoedini*)
 (pl. 49 A-M)
- Hypopharynx with a sclerome at base; mandible asymmetrical 43
43. Mola of mandible depressed, and with a grinding surface on the ventral side or on both the dorsal and ventral sides. (Presternum of prothorax usually elliptical and transverse) *Mycetophagidae* (pl. 50 A-T)
- Mola not depressed, and with a grinding surface facing the buccal cavity 53
44. Urogomphi present 45
- Urogomphi absent. (Paired ambulatorial warts usually well-developed dorsally and ventrally on anterior body segments; mandibles asymmetrical) *Oedemeridae-Oedemerinae* (pl. 51 A-F)
45. Ambulatorial warts present ventrally on second to fifth abdominal segments. (Mandibles symmetrical; urogomphi simple and curved upward, a pit present between their bases;

group Anthicidae and the mandibles and hypopharyngeal sclerome in the Byturidae are rather similar to the same structures of the Languridae (pl. 28 I, J, N) indicating close affinity between these families.

LARVAL FORMS OF COLEOPTERA

- ninth abdominal segment ventrally with two to three points on each side; maxillary mala with terminal incision)
- Oedemeridae - Calopodinae* (pl. 51 G-M)
- Ambulatorial warts absent 46
46. Ninth abdominal venter simple, without conical points 47
- Ninth abdominal venter with a conical point on each side 48
47. Submentum and gula fused and heavily chitinized. (Urogomphi well-developed, but white and rather soft)
- Cephaloidae* (pl. 52 J-L, N, O)
- Submentum and gula fleshy. (Urogomphi corniform, strongly chitinized and curved upward)
- Zopheridae* (*Zopherus*, *Zopherodes*, *Phelopsis* and *Phloeodes*)^{52a} (pl. 52 F-I, M)
48. Urogomphi simple, corniform, and curved upward; spiracles annular-biforous *Synchroidae* (*Synchroa*)⁵⁰ (pl. 52 A-E)
- Urogomphi with a branch at base; spiracles annular
- Pedilidae* (*Eurygenius*) (pl. 53 A-H)
49. Venter of ninth abdominal segment with transverse row of asperities, or of small plates 50
- Venter of ninth abdominal segment not so armed. (Hypopharynx fleshy; each urogomphus broadly bifurcate; spiracle biforous) *Salpingidae* (*Rhinosimus*)^{52b} (pl. 54 A-H)
50. Eighth abdominal segment at least twice as long as ninth, urogomphi excluded; a pair of pits in margin between urogomphi 51
- Eighth and ninth abdominal segments subequal, urogomphi excluded; a single pit present in margin between urogomphi. (Asperities of ninth abdominal venter in a broken arch) 52
51. Ninth abdominal venter bearing asperities arranged in a continuous arch *Pyrochroidae* (pl. 53 I-K and L-O)
- Ninth abdominal venter bearing small plates in place of asperities *Boridae* (*Boros unicolor*)⁵³ (pl. 48 G-K and 55 A-I)

^{52a} The genera of the family Zopheridae are usually placed in the tribes Zopherini and Nosodermini of the family Tenebrionidae.

^{52b} Usually considered as a separate subdivision of the family Pythidae.

⁵³ According to the characters of the imago the genus *Boros* has been placed either in the Tenebrionidae or in the Pythidae by most of the authors, but according to the characters of the larva it is considered by R. A. St. George (Proc. Ent. Soc. Wash., vol. 33,

LARVAL FORMS OF COLEOPTERA

52. Ninth abdominal segment dorsally with a continuous row of small dark tubercles on the urogomphi and on the space between them. (Each urogomphus with or without a toothlike spine on innerside) *Pythidae* (pl. 54 I-O)
- Ninth abdominal segment without a continuous row of tubercles; only with two small tubercles proximally on dorsal side of each urogomphus. (Each urogomphus with a large, toothlike spine medianly on innerside) *Othniidae* (= *Elacatidae*) (pl. 47 J-R)
53. Antenna contiguous to mouth frame. (Prothoracic legs frequently larger and thicker than those of meso-and metathorax, prothoracic coxae usually contiguous) 54
- Antenna inserted some distance in from mouth frame. (Prothoracic legs not larger and thicker than the other legs, and coxae not contiguous) 56
54. Back of mandible opposite the cutting edge with sharp margin; opposite the mola, excavate and without a spinose-setose elevation. (Hypopharyngeal sclerome tricuspidate with median portion bifid and strongly projecting; ninth abdominal segment without urogomphi, except in *Omophlus proteus* Kirsch, from Russia) 55
- Back of mandible not as described above. (Hypopharyngeal sclerome variable in form; ninth abdominal segment with or without urogomphi) *Tenebrionidae* (pls. 57 A-U and 58 A-K)
55. Ventro-lateral suture distinct *Alleculidae-Alleculinae* (pl. 56 A-L)
- Ventro-lateral suture absent *Alleculidae-Omophlinae* (pl. 56 M, N)
56. Molar part of mandible with the grinding surface transversely multicarinate; antenna short and two-jointed, second joint dome shaped and almost completely membranous *Nitionidae* (pl. 59 A-M)
- Molar part of mandible with the grinding surface either smooth, or bearing obtuse tubercles; antenna elongate and two- or three-jointed, second joint usually elevata, distal joint minute and dome-shaped, or absent. (Presternum large and triangular; with or without strong, straight, pointed urogomphi) *Lagriidae* (including the heterotarsine genera *Anaedus*, *Paratenetus* and *Lyprops*) (pl. 60 A-P)

1931, pp. 103-113; 2 plates) as the type of a separate family *Boridae*, thus substantiating the view of Thomson who in 1859 established this family on adult characters.

LARVAL FORMS OF COLEOPTERA

H. BYRRHOIDEA

The series contains only one family, the Byrrhidae. The genus *Nosodendron* is often placed in this family but belongs, according to the larval characters, in the subsequent series Dascilloidea, constituting a special family, Nosodendridae (p. 44).

KEY TO SUBFAMILIES

1. Distal half of the mandibular inner edge entire between the tip and a low tooth at the middle of the edge

Byrrhidae-Byrrhinae (pls. 61
A-K, 62 A-B, D-H)

Distal half of the mandibular inner edge multidentate 2

2. Tenth abdominal segment with a pair of hooks

Byrrhidae-Amphicyrtinae (pl.
62 C, I-L)

Tenth abdominal segment without hooks. (Labrum with anterior margin deeply emarginate sagittally)

Byrrhidae-Liooninae (pl. 62
M-R)

I. DASCILLOIDEA

This series does not conform with the series named Dascilloidea in the classification of the imagines but it has been considered expedient to retain the old serial name in the present tabulation of families which according to the larvae seem properly associated with the genus *Dascillus*. The larval characters of the Eucinetidae indicate that this family belongs in the series Cucujoidae (p. 33), or possibly in the leptinid association of the Staphylinoidea near the family Ptiliidae (p. 26).

KEY TO FAMILIES AND SUBFAMILIES

1. Eighth abdominal segment of normal form and not terminal; ninth abdominal segment large; spiracles cibriform. (Nine pairs of spiracles always present and all lateral)..... 2

Eighth abdominal segment large and terminal; ninth abdominal segment vestigial; spiracles annuliform or biforous. (Either with nine pairs of spiracles present and well developed, or with all vestigial except those on eighth abdominal segment; the latter large and close together below posterior end of eighth tergite) 3

2. Tenth abdominal segment almost obliterated and without soft, terminal prolongation; ocelli absent; antenna long; maxil-

LARVAL FORMS OF COLEOPTERA

lary articulating area large and cushioned; hypopharyngeal scleromes asymmetrical, strong, and much differentiated

Dascillidae (*Dascillus*) (pl. 63 A–I)

Teuth abdominal segment well-developed, with soft, terminal, unpaired, two-jointed, and retractile prolongation (anus placed immediately below ninth abdominal tergite); five ocelli on each side; antenna short; maxillary articulating area rather small and indistinct; hypopharyngeal scleromes symmetrical, of moderate strength, and not very much differentiated *Heteroceridae*⁵⁴ (pl. 64 A–M)

3. Spiracles vestigial or absent, except an annuliform pair on eighth abdominal segment; three terminal tufts of gills retractile into a pocket without an operculum; antenna multiarticulate and very long; one large ocellus and one small ocellus on each side (Mandible dimorph)

Helodidae (pl. 65 A–H)

Spiracles all present and biforous; gills absent; antenna three-jointed and of moderate length; five ocelli on each side

*Nosodendridae*⁵⁵ (pl. 66 A–P)

J. DRYOPOIDEA

This series does not conform with the series named Dryopoidea in the classification of the imagines but it has been considered expedient to retain the old serial name in the present tabulation of several families which according to the larvae are associated with the genus *Dryops*.

KEY TO FAMILIES AND SUBFAMILIES

1. Terminal cloacal chamber and movable operculum absent 2
- Terminal cloacal chamber present and furnished with three tufts of retractile gills and with a movable operculum below ninth abdominal tergum 5
2. Body cylindrical; without ventral gills (except in an Asiatic larva probably belonging to the Ptilodactylidae); spiracles biforous 3
- Body flat, broadly oval, limpetlike; with five pairs of ventral gills freely exposed from second to sixth abdominal segments; spiracles annuliform 4
3. Antenna comparatively long; tenth abdominal segment with a pair of large lobes usually carrying spinose diverticiles. (In

⁵⁴ The family Heteroceridae is usually placed, according to the characters of the imagines, in the series Dryopoidea.

⁵⁵ The taxonomic position of this family is much debated but, according to the characters of the imagines, it is usually placed in the series Byrrhoidea.

LARVAL FORMS OF COLEOPTERA

- Anchyrtarsus* with, and in *Ptilodactyla* without, gills from tenth abdominal segment) *Ptilodactylidae*⁵⁶ (pls. 67 A-J, 68 A-H, 69 A-H)
- Antenna short; tenth abdominal segment without diverticules.
(Gills lacking) *Eurypongidae*⁵⁶ (pl. 69 I-S)
4. Lateral expansions of eighth abdominal segment present
Psephenidae - *Eubrianacinae*⁵⁷
(pl. 70 A-E, G)
- Lateral expansions of eighth abdominal segment absent
(Mandible dimorphic in the same species, either simple, rather short, and terminally truncate, or composed of a basal and a terminal, pointed portion)
Psephenidae - *Psepheninae* (pl. 70 F, H-P)
5. Nine pairs of spiracles present, all projecting and either cribiform, or biforous but of a deviating sinuous type. (One ocellus on each side; ninth abdominal segment conical, or subconical and terminally bifurcate; appendix from operculum short and broad) *Chelonariidae*⁵⁸ (pl. 71 A-J)
- Spiracles present in a number varying from one to nine pairs, either annuliform or regularly biforous, never sinuous 6
6. Five ocelli on each side. (Body subcylindrical; mandible apically bidentate; ninth abdominal tergite terminally emarginate) *Dryopidae-Larinae* (*Lara*) (pl. 72 A-I)
- One large ocellus on each side 7
7. Head concealed beneath prothoracic dorsal shield; ninth abdominal segment dorsally flattened, more or less semicircular, or subrectangular. (Mandibles either simple and terminally obtuse, or terminally tridentate, or composed of a basal and a terminal pointed portion)
Dryopidae-Pelonominae (*Pelonomus*, *Helichus*, and *Psephenoides*) (pls. 70 Q-V, 72 J-K, 73 F-O)
- Head exserted and visible from above; ninth abdominal segment subconical, often distally fureate. (Mandibles terminally tridentate)
- ⁵⁶ According to the characters of the imagines, the Ptilodactylidae, including *Anchyrtarsus* and *Ptilodactyla*, and the Eurypongidae, including *Eurypong*, are usually placed in the series Dascilloidea.
- ⁵⁷ The subfamily Eubrianacinae, based on the genus *Eubrianax*, is usually placed in the Dascilloidea.
- ⁵⁸ The family Chelonariidae is usually placed in the series Dascilloidea.

LARVAL FORMS OF COLEOPTERA

nally bidentate or tridentate, alternating in some dimorphic species with rather short and terminally truncate ones)

Dryopidae - Helminae (*Dryops*,
Helmis, *Limnius*, *Ancyronyx*,
etc.) (pls. 71 K-Z, 73 A-E)

K. CANTHAROIDEA

KEY TO FAMILIES AND SUBFAMILIES

1. Ninth abdominal segment posteriorly with unpaired pointed prolongation, or paired urogomphi; body with featherlike or spinose processes. (Nasale posteriorly limited by a faint line; epieranial halves meeting ventrally; subfacial sinus of epieranium for the reception of the ventral mouthparts present; mandibles inserted well apart, falciform, canaliculate and without retinaculum; galea one-jointed) 2
Ninth abdominal segment without unpaired posterior prolongation and without paired urogomphi; body without conspicuous processes 3
2. Frontal sutures present; cardo present; gular suture long; second antennal joint enlarged; ninth abdominal segment posteriorly tapering into a long, spinose prolongation; body dorsally with spinose warts, laterally with featherlike prolongations *Brachypsectridae* Blair⁵⁹ (pls. 74 A-F, 75 A)
Frontal sutures absent; cardo absent or completely membranous; gular area very short; second antennal joint not enlarged; ninth abdominal segment with paired urogomphi; body with spinose, dorsal, or dorsal and lateral, prolongations. (Spiracles in small separate epipleural projections or plates) *Drilidae* (*Drilus* and *Silasia*)⁶⁰ (pls. 74, G-N, 75 B-E, 77 A)

⁵⁹ Blair, K. G., *Brachypsectra*, Lee.—The Solution of an Entomological Enigma, Trans. Ent. Soc. London, June 30, 1930, vol. 78, pp. 45-50, one plate.

The family *Brachypsectridae*, Blair, is considered a valid family according to the characters of the larva but, following H. S. Barber, it is here placed in the series Cantharoidea. It has close affinities to the larvae of *Drilus* and *Silasia*. The suggestion of Blair to join it with the Elateroidea has not been followed even if it unquestionably has close affinities with this latter series and particularly with the subfamily Cardiophorinae. In agreement with Blair, the usual conception of *Brachypsectra* as dasilloid is here disregarded.

⁶⁰ *Drilus* has polymorphic metamorphosis, the last instar of this snail-eating larva being maggotlike with a white, soft body and

LARVAL FORMS OF COLEOPTERA

- 3. Epicranial halves meeting ventrally forming a transverse bridge 4
- Epicranial halves not meeting ventrally. (Subfacial sinus incomplete or not present; tenth abdominal segment bearing retractile appendices) 8
- 4. Nasale long, spatulate, distally with median emargination; ventral epicranial bridge narrow and band-shaped; cardo absent; body segments with dorsal shields⁶¹

Homolidae

- Nasale short; ventral epicranial bridge broad, sagittally about half as long as cranium; cardo present; body segments fleshy, with velvety pubescence interspersed with fine setae. (Thoracic and most of abdominal segments with a pair of dorsal glands; subfacial sinus deep)⁶² 5
- 5. Mandible entirely without retinaculum; mandibular canal almost closed longitudinally, and distally having an oval opening. (Anterior margin of nasale projecting, substriangular, but without median grainlike tooth between a pair of longitudinal grooves) *Cantharidae-Malthinae* (pl. 77 B-G)
- Mandible with a large retinaculum (except in *Podabrus*, where it is small and tuberculiform); mandibular canal open longitudinally and without a special distal opening 6
- 6. Maxilla without free, jointlike galea; anterior nasal margin multi-serrate without a median grainlike tooth visible from above *Cantharidae - Chauliognathinae* (pl. 78 A-I)
- Maxilla with free, conical, one- or two-jointed galea; anterior nasal margin straight with a projecting median grainlike tooth between a pair of short longitudinal grooves 7

very reduced membranous antennae, mouthparts and legs. The characterization given above refers to the larval instars prior to the last one. See article by E. C. Rosenberg (Ent. Medd. Ser. 2, vol. 3, 1909, two plates).

⁶¹ Bertkau, P., Deut. Ent. Ztschr., 1891, pp. 37-42, one plate.

Verhoeff, K. W., Zur Kenntnis der Canthariden-Larven, Archiv für Naturgeschichte, vol. 89, A, Heft 1, 1923, pp. 110-137, one plate.

⁶² According to Verhoeff, K. W. (Zur Entwicklung, Morphologie und Biologie der Vorlarven und Larven der Canthariden, Archiv. für Naturgeschichte, vol. 83, A, Sept. 2, 1917, pp. 102-140, one plate), foetometamorphosis occurs in members of the family Cantharidae, two free-living foetal instars with vestigial antennae, mouthparts and legs appearing before the first real larval instar. This first instar itself differs only in minor characters, for instance in the proportional length of the joints of the antennae and the maxillary palpi, from the rest of the larval instars.

LARVAL FORMS OF COLEOPTERA

7. Second antennal joint prolonged distally on the inner side into a cylindrical process carrying the apical joint; cylindrical process of second joint of about the same length or longer than basal portion of joint; sensory appendix large; inner margin of mandible without a longitudinal series of setae

Cantharidae-Malthodinae (pl. 77
I, K, L)

Second antennal joint without a distinct cylindrical process; inner margin of mandible ventrally and medianly with a longitudinal series of short, densely set setae. (Retinaenulum either with (in *Silis*) or without (in *Cantharis* and *Poda-brus*) a small tooth posteriorly at base)

Cantharidae-Cantharinae (pl. 77
H, J, M-U)

8. Frontal sutures present; abdominal spiracles placed in the epipleural plates. (Mandibles separate at base, perforated by a longitudinal canal, and often associated proximally with an ear- or tooth-shaped hairy enlargement; retinaculum present, but very small in a few forms as *Photinus*; luminous organs usually present; saclike gills from sides of first to eighth abdominal segments present in some aquatic Lampyrid larvae) *Lampyridae*⁶³ (pls. 74 O-V, 75 F-H)

Frontal sutures absent; abdominal spiracles placed in the parascutal areas above the epipleura. (Mandibles either separate or meeting at base; retinaculum absent) 9

9. Stipes and mentum separate; cardo present; galea palplike and two-jointed; mandibles separate, perforated by a longitudinal canal; antenna three-jointed with apical joint and disk shaped appendix. (Luminous organs usually present)

Phengodidae (pls. 74 W-X, 75 I-K)

Stipes and mentum fused; cardo vestigial or absent; galea one-jointed; mandibles meeting sagittally at base; each mandible cleft from tip to base, with the inner part dagger-shaped and sliding into an open canal in outer part; antenna one- or two-jointed, distally covered with a large, dome-shaped appendix (*Caeniella* with inflated, tubular dorsal projections)....

Lycidae (pl. 76 A-K)

LARVAL FORMS OF COLEOPTERA

L. ELATEROIDEA

KEY TO FAMILIES AND SUBFAMILIES

1. Labrum distinct. (Headcapsule and mouthparts neither reduced nor abnormal) 2
Labrum and clypeus fused, forming a nasale immovably united with frons. (Spiracles biforous) 6
2. Spiracles biforous; ninth abdominal segment opercular; body cylindrical and strongly sclerotized; legs distinct
Rhipiceridae (*Zenoa*) (pl. 79 A-H)
Spiracles cribiform; ninth abdominal segment well-developed and not opercular; body fleshy, with a dorsal and a ventral plate of the same shape, more or less covering a flattened and enlarged prothorax; legs absent or very much reduced. (Chordotonal organs often very distinctly indicated laterally on many of the segments by a deep auditory pit) 3
3. Prothorax only slightly broader or even slightly narrower than the first abdominal segments; larva either spindle-shaped (*Pachyschelus*), or wedge-shaped and with transverse anus (*Brachys* and the European *Trachys*). (Leaf miners)
Buprestidae-Pachyschelinac (pl. 80 A-D)
Prothorax distinctly broader than the first abdominal segments; larva clublike and somewhat flattened; anus a longitudinal slit 4
4. Tenth abdominal segment large, terminating with a pair of pointed and hard prolongations
Buprestidae-Agrilinae (*Agrilus*, *Eupristocerus*) (pl. 80 E)
Tenth abdominal segment rounded, often with a pair of soft warts but without strong, hard prolongations 5
5. Dorsal plate of prothorax with or without asperities, medianly marked with an inverted Y- or V-shaped groove
Buprestidae-Buprestinae (*Chalcophorini*, *Buprestini*, *Chrysobothrini*) (pl. 80 F-K)
Dorsal plate of prothorax without asperities and marked medianly with an I-shaped groove
Buprestidae-Polycestinae (*Polycestini*, *Thrinopygini*)
6. Headcapsule and mouthparts very much reduced or extremely specialized. (Prothorax ventrally, or both dorsally and ventrally, with a pair of separate, rod-shaped, longitudinal scleromes often of a form suggesting a figure 7 or a letter T) 7

LARVAL FORMS OF COLEOPTERA

- Headcapsule and mouthparts slightly reduced or entirely normal 8
7. Legs short but with normal joints
*Throscidae*⁶⁷ (pl. 81 A-D)
 Legs vestigial or absent *Melasidae* (= *Euenemidae*) (pl. 81 H-Q) 9
8. Gular area well-developed and quadrangular 9
 Gular area small and indistinct, or represented only by a median, long or short gular suture 10
9. Larva strongly sclerotized; dorsal and ventral prothoracic scleromes united into a solid cylinder; cervical membrane very large and eversible forming a balloon-shaped sack below the head when raised *Cebriionidae* (including former family *Plastoceridae*⁶⁴) (pl. 79 I-P)
- Larva white and soft-skinned; dorsal and ventral prothoracic parts not forming a cylinder; cervical membrane not eversible. (Antenna and labial palpus one-jointed; legs small and three-jointed). (Parasitic in immature stages of cicadas) *Sandalidae*⁶⁵ (pl. 82 A-G) 10
10. Abdomen entirely soft-skinned; typical abdominal segments transversely divided into three, ring-shaped portions of almost equal length; median portion subglobular, bearing ampullae and spiracles. (Tenth abdominal segment with three digitate or palmate and retractile appendices; mandible deeply cleft into a dorsal, dentate, and a ventral, simple part) *Elateridae - Cardiophorinae* (pl. 83 A-O)
- Abdomen completely or partially sclerotized; abdominal segments not divided into three ring-shaped portions of almost equal length 11
11. Ninth abdominal segment in front of terminal urogomphi with a pair of dorsal, distantly placed, curved prongs with concavities facing either toward each other (*Drapetes*) or backward and downward (*Oestodes*). (Nasale bilobed; frons broadly attaining the occipital foramen)⁶⁶
Elateridae - Oestodinae (pl. 83 P-Y)

⁶⁴ Hyslop, J. A., Proc. Ent. Soc. Wash., vol. 25, 1923, pp. 156-160, one plate.

⁶⁵ The family is distinctly different from the family Rhipiceridae. Craighead, F. C., Proc. Ent. Soc. Wash., vol. 23, 1921, pp. 44-48, one plate.

Emden, F. von, 3 Wanderversammlung deutscher Entomologen in Giessen, 1929, p. 115.

⁶⁶ *Drapetes* is usually placed in the family Throscidae. An unidentified elateroid larva, found in a decayed red oak log from

LARVAL FORMS OF COLEOPTERA

- Ninth abdominal segment without dorsal prongs in front of urogomphi 12
12. Body dorsoventrally flattened; ninth abdominal tergite either with a pair of well-separated urogomphi or a single biramous process (pls. 84 G, 85 O); tenth abdominal segment more or less produced and often bearing hooks or other armature *Elateridae - Pyrophorinae* (pls. 84 A-S, 85 A-R, 86 A-E)
- Body more or less cylindrical; ninth abdominal tergite without urogomphi; tenth abdominal segment small, not produced, and never bearing armature
Elateridae - Elaterinae (pl. 86 F-U)

M. SCARABAEOIDEA

KEY TO FAMILIES AND SUBFAMILIES

1. Stridulating organs present on second and third pairs of legs (pl. 87 E, I); abdominal terga not plicate. (*Lacinia* and *galea* separate (pl. 87 B, F)) 2
- Stridulating organs absent, or present as teeth on dorsal inner margin of maxillary stipites, usually working against a granulate or striped area on ventral side of mandibles; (pl. 88 M, P) abdominal terga plicate. (*Lacinia* and *galea* separate or fused (pl. 87 V)) 7
2. Anus longitudinal between two large, oval, often sclerotized pads at end of body (pl. 87 J); third pair of legs normal 3
- Anus transverse; end of body different; third pair of legs reduced and much shorter than second pair 6
3. Dorsal shield of prothorax anteriorly on each side with a triangular, forwardly directed process
Lucanidae - Sinodendrinae (pl. 87 I, J)
- Dorsal shield of prothorax without process 4
4. Left mandible in front of molar part with two (*Nicagus*) or three teeth (*Ceruchus*) *Lucanidae-Aesalinae* (pl. 87 K)
- Left mandible in front of molar part with four or five teeth 5
5. Tenth abdominal segment slightly hairy dorsally; claw somewhat curved; left mandible either with four (*Platycerus*) or five teeth (*Dorcus*) *Lucanidae-Dorcinae*
- Tenth abdominal segment hairy dorsally; claw strong and straight; left mandible with five teeth
Lucanidae - Lucaninae (pl. 87 A-D)

North Carolina, probably belongs in or near the *Oestodinae* but it also possesses characters, present in the ventral mouthparts and the sternal region of prothorax, which approach it to the *Throscidae* (pl. 81 E-G).

LARVAL FORMS OF COLEOPTERA

6. Mandible without ventral accessory condyle; antenna and maxillary palpus two-jointed; abdominal terga without numerous spines or hairs; dorsal and ventral anal lobes small, ventral lobe with a pair of elongate lanceolate pads

Passalidae (pl. 87 E-H)

Mandible with accessory ventral condyle; (pl. 88 J) antenna and maxillary palpus more than two-jointed; abdominal terga with numerous spines or hairs; dorsal anal lobe semi-circular, ventral anal lobe laterally grooved and much broader than dorsal *Geotrupidae*

7. Lacinia and galea separate 8
 Lacinia and galea fused 16
 8. Stridulating organs absent (pl. 87 X) 9
 At least maxillary stridulating teeth present (pl. 87 V) 10
 9. Labrum sometimes anteriorly bilobed with a median emargination, usually subtriangular with rounded corners; anal lobes swollen, the dorsal entire, the ventral with median groove; (pl. 87 M, T) raster⁶⁷ without longitudinal or transverse series of setae; some species with biforous spiracles, as found in *Trox seaber* L. from Europe (pl. 87 Q, R) *Trox unistriatus* Beauvois and *Trox aequalis* Say, others with cibriform spiracles, as found in *Trox oligomus* Loomis (pl. 87 S); claw long and pointed, antenna with three joints, two normal and the terminal minute

Trogidae (pl. 87 L-T)

Labrum with distinctly multiserrate anterior margin; anal lobes normal; raster⁶⁷ with a single transverse row of spatulate setae; spiracles cibriform; claw normal; antenna four-jointed *Acanthoceridae* (*Cloeotus*)

10. Dorsal and ventral anal lobes swollen. (Ventral lobe medianly divided by a longitudinal groove) 11
 Anal lobes not particularly swollen. (Anus transverse and straight, or V-shaped) 15
 11. Legs incomplete, claws absent or minute on all legs; abdomen strongly humped dorsally 12
 Legs complete, with normal claws; abdomen not humped 14
 12. Legs distinctly two-jointed (consisting of a long coxa and a still longer, strongly pointed joint with a terminal seta; terminal joint with shallow, annulate constrictions but not bent at the middle) *Scarabaeidae-Coprinae, part one*
(Onthophagus)
 Legs distinctly or indistinctly three-jointed 13
 13. Coxa, femur, and tibia distinct and all of the same length; tibia conical and ending bluntly; no claw

Scarabaeidae-Coprinae, part two
(Canthon)

⁶⁷ The term "raster," meaning a rake, applies to a spinose area on the ventral side of the tenth abdominal segment (pl. 88 A, C, H).

LARVAL FORMS OF COLEOPTERA

Coxa distinct, femur and tibia apparently fused but forming an angle with each other; claw minute (no terminal seta)

Scarabaeidae - Coprinae, part three (Copris)

14. Raster with a longitudinal series of strong, simply pointed or tricuspidate spines on each side of middle line

Scarabaeidae - Aphodiinae, part one (Aphodius rufipes group)

Raster without paramedian series of spines

Scarabaeidae - Aphodiinae, part two (Aphodius fessor group)

15. Claw very long and pointed, longer than tibia; head flat above; body woolly; anus transverse

Scarabaeidae - Glaophyrinae (Lichnanthe)

Claw moderately long, shorter than tibia; head convex above; dorsal areas densely beset with short, strong, dark setae; anus angulate *Scarabaeidae - Placocominiae*

16. Anus obtusely or acutely angulate, usually V- or Y-shaped (pl. 88 H). (Mandibular stridulating area without distinct outline and formed by minute granulations (pl. 88 J); sometimes entirely absent) 17

Anus transverse, not angulate (pl. 88 C). (Mandibular stridulating area oval and formed by transverse striae; absent in *Valgus*) 21

17. Raster with two longitudinal rows of pointed setae

Scarabaeidae - Melolonthinae - Melolonthini

Raster without two longitudinal rows of pointed setae 18

18. Raster with transversely arranged setae 19

Raster with setae placed without order 20

19. Setae arranged in a transverse mustachelike patch

Scarabaeidae - Melolonthinae - Diplotaxini

Setae spinelike, arranged in a single transverse, curved row

Scarabaeidae - Sericinae (pl. 88 H-L, N)

20. With large patch of closely set asperities on each side of raster

Scarabaeidae - Macrodactylinae - Dichelonycini

Without patch of asperities on each side of raster

Scarabaeidae - Macrodactylinae - Hoplini (Macrodactylus and Hoplia)

21. Epipharynx without a curved single row of small spines parallel with and behind the median part of the anterior

LARVAL FORMS OF COLEOPTERA

- margin of labrum. (Stridulating organs present, terga of ninth and tenth abdominal segments distinguishable; labrum usually asymmetrical and not trilobed) 22
- Epipharynx with a curved single row of small spines behind the median part of the anterior margin of labrum (pl. 87 Z) (except in *Valgus* which, however, has no stridulating organs). (Terga of ninth and tenth abdominal segments usually fused completely; labrum symmetrical, often trilobed) 24
22. Lateral margin of labrum on buccal side with a series of transverse striae (pl. 88 D) *Scarabaeidae-Rutelinae-Anomalini* (pl. 88 B-D, F, G)
- Lateral margin of labrum on buccal side without striae (pl. 87 U) 23
23. Stridulating teeth of maxillary stipes pointed and curved (pl. 87 V). (Distal joint of maxillary palpus usually without a setaceous sensory area) *Scarabaeidae-Rutelinae-Rutelini* (pls. 87 U, V, 88 A)
- Stridulating teeth of maxillary stipes truncate, as broad as long, not curved (pl. 88 M). (Distal joint of maxillary palpus often ending in a setaceous sensory area)
- Scarabaeidae-Dynastinae* (pl. 88 E, M, O-R)
24. Anterior margin of labrum not distinctly trilobed, almost straight or slightly emarginate in the middle (pl. 87 W, Y); ninth and tenth abdominal terga separated; tarsungulus long and pointed 25
- Anterior margin of labrum distinctly trilobed (pl. 87 Z); ninth and tenth abdominal terga fused into a single dorsal unit; tarsungulus different 26
25. Raster present, with numerous, minute, dark spinulae between the longer setae; epipharynx with triangular callus and a curved transverse series of small spines behind the anterior margin of labrum (pl. 87 Y)
- Scarabaeidae-Trichiinae* (*Trichiotinus*, *Trichius*, *Trigonopeltastes*, *Gnorimella*) (pl. 87 Y)
- Raster absent, end of abdomen with long, soft hairs; epipharynx without a triangular callus and without a curved series of spines behind the anterior margin of labrum. (Labrum strictly symmetrical, slightly emarginate in the middle) *Scarabaeidae-Valginae* (*Valgus*) (pl. 87 W, X)
26. Tarsungulus cylindrical, distally obtuse (except in *Euphoria*); raster with median pair of distinct, longitudinal series of spines *Scarabaeidae - Cetoniinae, part one* (*Gymnetini* and *Cetoniini*) (pl. 87 Z)

LARVAL FORMS OF COLEOPTERA

Tarsungulus short, thick, conical; raster without a pair of longitudinal series of spines

Scarabaeidae - Cetoniinae, part two, (Cremastocheilini and Osmodermini; the latter tribe usually placed in the Trichiinae)

N. CLEROIDEA

KEY TO FAMILIES AND SUBFAMILIES

1. Frontal sutures present 2
- Frontal sutures absent. (Apex of mandible with two or more teeth; endoparasitic, physogastric larvae) 16
2. Lacinia distally armed with one or more spurs. (Body covered with long or short barbed hairs) 3
- Lacinia without spurs 4
3. Paired urogomphi present; submentum and gular areas united; mandible with a stiff process and a hair brush at base
Dermestidae - Dermestinae (pl. 89 A-Q)

Urogomphi absent; submentum and gular areas usually separated; mandible without spur and brush at base. (Larvae often with conspicuous hair tufts)

Dermestidae - Attageninae (pl. 90 A-Z)

4. Ventral mouthparts retracted. (Distance between posterior ends of cardines and occipital foramen usually shorter than frons) 5
- Ventral mouthparts protracted. (Distance between ends of cardines and occipital foramen as long as frons) 8
5. Mandible with a long, stiff prosthecal process near the middle or at the base of the inner margin. (Median epicranial suture well developed) *Melyridae* (pls. 91 A-N, 92 A-J)

Mandible with a short or no prosthecal process. (Median epicranial suture usually not well developed, or entirely absent) 6

6. Antenna with the sensory appendix longer than the distal joint. (Distal joint carrying a very long and strong terminal seta *Ciidae*⁶⁸ (pl. 92 K-R)
- Antenna with sensory appendix shorter than distal joints, or absent 7

⁶⁸ According to the characters of the imagines, the systematic position of this family is not clear, but usually it is placed in the series Bostrichoidea. In the larvae, the division of the mala into a lobe-like galea and a smaller lacinia hidden below the galea sug-

LARVAL FORMS OF COLEOPTERA

7. Prothorax with well-separated presternal plates and with a well-defined lanceolate median sternal plate
Ostomatidae-Tenebroidinae (pls. 93 A-Q, 94 A-I)
- Prothorax without well-defined presternal plates and without a median lanceolate sternal plate
Ostomatidae - Ostomatinae (pl. 93 D, 94 J-U)
8. Frons posteriorly with straight, transversal margin
Cleridae-Hydnocerinae (pl. 95 B-H)
- Frons posteriorly angulate 9
9. Epicranial suture well developed
Cleridae-Thaneroclerinae (pl. 95 V)
 Epicranial suture not well developed 10
10. Antenna with second joint larger than basal joint; ninth abdominal segment conical, bifid. (One ocellus)
Cleridae-Priocerinae (pl. 95 P)
 Antenna with second joint shorter than basal; ninth abdominal segment otherwise 11
11. All spiracles large and biforous; two ocelli present on each side. (Prothorax with separated presternal plates and a median sternal plate) *Cleridae-Korynetinae* (*Necrobia* and *Korynetes*)
 Anterior or all spiracles annuliform or pseudo-annuliform; never with two ocelli present on each side. (Prothorax with or without presternal plates and median sternal plate) 12
12. Ocelli one (*Monophylla*) or three (*Cymatodera* and *Tillus*)
Cleridae-Tillinae (pl. 95 K, N, R, X)
 Ocelli absent, or four, or five 13
13. Ocelli absent. (Body tumid; without ambulatorial ampullae)
Cleridae-Orthopleurinae (pl. 95 S)
 Ocelli four or five 14
14. Two or more of abdominal segments with paired protruding dorsal ambulatorial ampullae; cardo with narrow, band-like basal sclerome 15

gests bostrichoid relationship, but a similar division is also found in some of the Cleroidea; and the presence of long and converging frontal sutures, a distinct gular area, paired urogomphi, and the absence of paired oval lobes in front of anus speak strongly against a taxonomic position within the Bostrichoidea and for the association with the Cleroidea.

LARVAL FORMS OF COLEOPTERA

- Paired ambulatorial ampullae absent; cardo with extensive sclerome *Cleridae-Clerinae* (*Opilo, Trichodes, Thanasimus, Enoclerus, Platynus, Placopterus*) (pl. 95 A, I, J, M, Q, T, U)
15. Ocelli five; more than two of abdominal segments with dorsal ambulatorial ampullae *Cleridae-Enopliinae* (*Neichneus, Phyllobaenus, Chariessa, Cregya*) (pl. 95 O)
- Ocelli four; only two abdominal segments with ambulatorial ampullae *Cleridae-Tarsosteninae* (pl. 95 L)
16. Antenna with sensory appendix absent; ventral mouthparts apparently protracted; ventral surface of head apparently formed by fusion of the gular region and the cranial capsule; hypostomata rod-shaped and diverging posteriorly from the fossae for the mandibles *Catogenidae*⁶⁹ (pl. 33 I, J, L, M, O)
- Antennae with sensory appendix present, dilated, and as long as distal and median joints together; ventral mouthparts retracted; gular area distinct, not fused with head capsule; hypostomata not rod-shaped, and not diverging, but curved toward each other *Bothrideridae*⁷⁰ (pl. 44 F-W)

⁶⁹ The family Catogenidae, composed of the genera *Scalidia* and *Catogenus*, is placed by most authors, and probably correctly, near genera as *Laemophloeus* and *Hemipeplus* in the series Cucujoidae. The characters defining the larvae as belonging to the series Cleroidea are probably not fundamental but result from adaptation to a parasitic life. The straight, pointed, rod-shaped hypostomata which diverge from the mandibular fossae in a posterior direction are similar to the ones found in *Laemophloeus*, *Hemipeplus*, and the Phalaecidae, and this similarity indicates strongly that the large subfacial region between the rod-shaped hypostomata in the Catogenidae is homologous with the region between the rod-shaped hypostomata in the above-mentioned cucujoid larvae and particularly with the one in the Phalaecidae. Thus the ventral surface of the head in the Catogenidae is probably formed by a fusion of the ventral sides of the cranial capsule, a pair of cardines, the submental region between them, and a gular area posteriorly. The family Catogenidae has therefore been tabulated also on page 35 in the series Cucujoidae.

⁷⁰ The relationship of this family is problematic. It has also been tabulated near the Colydiidae on page 40 in the series Cucujoidae where it most likely has its proper systematic place. However, the larvae are quite different from the larvae of the typical Colydiidae. Their head structures, at least, suggest cleroid affin-

LARVAL FORMS OF COLEOPTERA

O. MELOIDEA

KEY TO FAMILIES AND SUBFAMILIES⁷¹

1. Gula well-developed; maxillae inserted considerable at a distance in from anterior margin of prosternum; labial palpi two-jointed 2
- Gular area short; maxillae extending posteriorly to near the anterior margin of prosternum; labial palpi not jointed, reduced to warts, or entirely absent. (Antenna with terminal joint (tj pl. 97 D) long and slender, and distal sensory appendix (sj pl. 97 D, E) either long, slender and conical, or long and sausage-shaped 5
2. Head capsule subquadrate, with ocelli usually in anterior third; labrum small, visible from above; integument on ventral side of body thin. (All thoracic and abdominal spiracles usually of about the same size and sometimes very large; larva elongate, dorsoventrally flattened; mandible extending well beyond anterior margin of labrum; abdomen with subparallel sides or posteriorly attenuate; ninth abdominal segment terminally with one, rarely two pairs of long bristles). (Fifth instar coarctate, not enclosed in exuvium of previous instars; the free-living instars eating grasshoppers' eggs or carnivorous on bee larvae, rarely honey feeders; first instars not carried by bees) *Meloidae-Lyttinae* (pl. 96 A-I)
- Head capsule broadly oval (pl. 96 Q) or subtriangular (pl. 96 M) with ocelli in or behind its transverse middle line; labrum as a rule not visible from above; integument on ventral side of body firm. (First pair of abdominal spiracles usually larger than the others and as large as the mesothoracic). (Instars as a rule feeding on honey; first larval instar climbing flowers and carried by bees) 3
3. One ocellus on each side; ninth abdominal segment carrying terminally one or more pairs of long bristles (term. s. pl. 96 M); body elongate, dorsoventrally flattened with suboval or posteriorly attenuate abdomen. (Fifth larval instar coarctate, not developed in exuvium of preceding instars; sixth instar moving freely around) *Meloidae-Meloinae* (pl. 96 J, K, M, P, Q)

ities. (See Craighead, F. C., Proe. Ent. Soc. Wash., vol. 22, 1920, pp. 1-13, 2 plates. This paper contains a discussion of the taxonomic position of the Bothrideridae, Colydiidae and Monoedidae (auct.). The Monoedidae are not recognized as a family on the larval characters, but placed as a genus in the family Colydiidae.)

⁷¹ The key deals exclusively with the first larval instars of the series, except in a few cases in which it is definitely stated to which instars, different from the first, the references apply.

LARVAL FORMS OF COLEOPTERA

Two ocelli on each side (second ocellus small or even absent in species of Horiinae); ninth abdominal segment carrying terminally one pair of small bristles, or no bristles; body either fairly elongate with posteriorly attenuate abdomen, or more often, navicular. (Fifth larval instar enveloped in exuvia of the two preceding instars; sixth instar as well as pupa inside of case formed by the exuvia of the three preceding larval instars).....⁴

4. Spiracles of eighth abdominal segment placed normally

*Meloidae-Horiinae*⁷²

Spiracles of eighth abdominal segment placed terminally on hook- or wartlike projections (spw. pl. 96 N, O)

Meloidae-Nemognathinae (pl. 96 L, N, O, R, S)

5. One ocellus on each side of head; spiracle of first abdominal segment very large and placed on a laterally projecting, flat lobe (pl. 97 B and D); claw falciform, with a single bristle at base; labial palpi vestigial and wart-shaped⁷³

Tetraonycidae (Based on *Tetraonyx quadrimaculatus*) (pl. 97 A-D)

Several ocelli placed closely together on each side of head; spiracle of first abdominal segment normal and not placed on a projecting lateral lobe; claw rather short, at base with a large pulvillus (pon. pl. 97 F) and a very short, conical, thick seta; labial palpus absent. (Median dorsal suture absent on all body segments). (Either with the first larval instar carried by wasps and in all the feeding stages devouring wasp larvae in their cells, or parasitic on cockroaches)

*Rhipiphoridae*⁷⁴ (pl. 97 E-J)

⁷² According to the imagines, the Horniiae are usually placed as a tribe of the subfamily Zonitinae.

⁷³ According to the imagines, *Tetraonyx* is usually placed in the subfamily Lyttinae. According to the first instars reared from eggs laid by *Tetraonyx quadrimaculatus* Fab., this larva forms an intermediate type between the larvae of the family Meloidae and the family Rhipiphoridae but differs so distinctly from both of them that the creation of a new family, Tetraonycidae, is deemed advisable.

⁷⁴ The first instar of *Rhyzostylops*, described by F. Silvestri (Descrizione di un nuovo genere di Rhipiphoridae, Redia, vol. III, 1906, pp. 315-324, one plate) looks superficially like a *Stenus* larva, has long legs, said to be tipped by two extremely minute claws, several ocelli on each side of head, and is heavily bristled. It is considered by Silvestri as a very aberrant rhipiphorid larva, intermediate between the first instar of *Rhipidius* and the degenerate first instar of the Strepsiptera. Probably the Strepsiptera are to be classified in the Coleoptera and close to the Rhipiphoridae.

LARVAL FORMS OF COLEOPTERA

P. MORDELLOIDEA

In the Introduction to his Catalogue (p. 32) Leng proposed, with great hesitation however, a series Mordelloidea composed of the following groups: the Mordellidae-Mordellini, the Mordellidae-Anaspidini, the Anthicidae, the Euglenidae, the Eurystethidae (= Aegialitidae), the Pedilidae, the Pyrochroidae, the Pythidae (with the two genera *Salpingus* and *Rhinosimus* included), the Cephaloidae, the Oedemeridae, and, with proper reservation, the Meloidae and the Rhipiphoridae. Here only the Mordellidae-Mordellini with the main genera *Tomoxia*, *Mordella*, and *Mordellistena* have been retained in this series, and it is even questionable whether these really may constitute a series as their larvae seem rather closely related to the larvae of several of the melandryid genera. The Mordellidae-Anaspidini together with all of the above mentioned families from the Anthicidae to the Oedemeridae have been placed in the colydiid association of the Cucujoidea; and in this association are also placed the Othniidae with the genus *Othnius* and the Boridae with the genus *Boros* which are closely related to the Pyrochroidae and Pythidae. It is however, possible that the Anaspidae, Anthicidae, and Euglenidae might better be associated with the Languriidae. The Rhipiphoridae and the Meloidae constitute, according to the larvae, a separate series, the Meloidea. (See also: Introduction p. 8, line 9).

KEY TO FAMILY

1. Body without dorsal ambulatorial warts; ninth abdominal segment terminating with a single, conical, truncale spine

*Mordellidae, part one (Tomoxia,
Mordella, and the larva of
Mordellistena picipennis)* (pl.
98 A-E)

Body with dorsal ambulatorial warts; ninth abdominal segment with a pair of short, upward curved, pointed urogomphi *Mordellidae, part two (Mordellistena)* (pl. 98 F-J)

Q. CERAMBYCOIDEA

The series Cerambycoidea contains only one family, the Cerambycidae, which is divided into six subfamilies. Of these the subfamily Disteniinae should probably be given family rank because its larva, except in its general appearance, is very aberrant from the larval types of all of the other Cerambycidae. In fact the

LARVAL FORMS OF COLEOPTERA

Disteniinae might possibly with equal justification be placed in either of the two series, the Bostrichoidea or the Chrysomeloidea, both closely associated with the Cerambycoidea, rather than in the latter series. The larva of the Disteniinae differs from all other cerambycoid larvae in the development of the ventral structures of the head and chiefly in the lack of a distinct gula, but the presence of a short gula lying on top of the median part of a broad, well-defined hypostomal bridge and fused with it is just the essential character by which the larvae of the Cerambycoidea can be separated from the ones of the Bostrichoidea and Chrysomeloidea.⁷⁵

KEY TO SUBFAMILIES

1. Head oblong, sides parallel or converging behind. (Epistoma never projecting; tentorial cross-arm internal; epipleurum protuberant on several or all abdominal segments; legs usually absent) *Lamiinae* (pls. 99 I, J, 100 A)
Head transverse, wider behind the middle 2
2. Epistoma projecting over clypeus, except in *Parandra*; frons projecting over epistoma, dentate or carinate, except in *Parandra*. (Tentorial cross-arm in the same plane as the hypostoma and forming a bridge behind it; legs present) *Prioninae*⁷⁶ (pls. 99 A, B, 100 B-F)
Neither epistoma nor frons projecting 3
3. Mandible with oblique, straight cutting edge, except in *Opsimus* 4
Mandible with rounded, gougelike cutting edge (pl. 100 G). (Tentorial cross-arm in the same plane as hypostoma and forming a bridge behind it; clypeus filling space between dorsal articulations of mandibles; epipleurum protuberant only on last three abdominal segments; legs present or absent) *Cerambycinae* (pls. 99 E, F, 100 G)
4. Dorsal margins of epicranial halves partly fused behind frons. (Tentorial cross-arm internal; legs present) *Aseminae* (pl. 99 C, D)
Dorsal margins of epicranial halves separated behind frons 5

⁷⁵ Craighead, F. C., North American Cerambycid Larvae, Canada Dept. Agr., Bul. 27, New Series, Technical, Ottawa, 1923, pp. 6, 26, and 99-101 with figures.

⁷⁶ Craighead, F. C., Larvae of Prioninae, U. S. Dept. Agr., Off. Sec., Report 107, 1915, pp. 1-24, eight plates.

LARVAL FORMS OF COLEOPTERA

5. Tentorial cross-arm internal. (Palpiger large, bearing lacinia and palpus; epipleurum protuberant on all abdominal segments; legs present) *Lepturinae* (pls. 99 G, H, 100 II-L)

Tentorial cross-arm (tb pl. 100 M) in the same plane as the hypostoma, bridging the ventral surface of the head. (Larva very elongate and slender; legs present)

Disteniinae (pl. 100 M)

R. BOSTRICHOIDEA

KEY TO FAMILIES

1. Head protracted; mandible dentate. (Terga hairy or not, often with rows or patches of asperities) 2
- Head retracted; mandible not dentate, usually with gouge-shaped distal end. (Terga without asperities) 3
2. Thoracic spiracle pushed forward to anterior margin of prothorax. (Spiracles bearing a single spoutlike prolongation (prl pl. 101 E); a small, often curved, transverse sclerome present at the end of a median groove between the longitudinally placed anal lobes (ats pl. 101 G); terga without asperities) *Ptinidae* (pl. 101 A, B, E)

Thoracic spiracle not reaching anterior margin of prothorax. (Spiracles without single spoutlike prolongations, except in *Anobium*, where they are large; with or without a small, transverse sclerome at the end of a longitudinal, median anal groove; straight, curved, or hook-shaped tergal asperities on all or some of the segments, except in *Ozognathus* and *Lasioderma*) *Anobiidae* (pl. 101 C, D, F-N, X, Ae, Oe)

3. Mandible without a dorsal, molarlike process; epipharynx without a large sclerome; lacinia mandibulæ absent
..... *Bostrichidae*⁷⁷ (pl. 101 O-W, Y, Z)

Mandible with a dorsal, molarlike process, grinding against a large sclerome in epipharynx; lacinia mandibulæ present and fleshy 4

4. Abdominal spiracles subequal in size

*Psoidae*⁷⁸ (pl. 102 A-E)

⁷⁷ The family includes all the genera usually placed in the family Bostrichidae, except the genera which are here tabulated in the family Psoidae.

⁷⁸ The family Psoidae includes the following genera, usually placed in the Bostrichidae: *Stephanopachys* (Saalas, U., Die Fichtenkäfer Finlands, part 2, 1923, pp. 179 and 700, figs. 115-120), *Rhizopertha*, *Dinoderus*, and *Dinoderopsis* (Lesne, P., Les coléoptères Bostrychides de l'Afrique tropical française, Paris, 1924, pp. 47 and 77), *Polycaon*, and *Psoa*.

LARVAL FORMS OF COLEOPTERA

Last abdominal spiracle much larger than the others
Lyctidae (pl. 102 F-K)

S. CHRYSOMELOIDEA

KEY TO FAMILIES AND SUBFAMILIES

1. Mandible simple, distally either with a broad, transverse, gougelike cutting edge, or with a simple apex 2
- Mandible dentate, distally with from two to five teeth 5
2. Prementum and mentum fused, bearing a common, median, escutcheonlike sclerome with a pair of light, circular areas anteriorly. (Labial palpi either (in Pachymerinae) rudimentary, one-jointed, and placed in the light, circular areas of the escutcheon (pl. 103 D), or (in Bruchinae) completely absent; mandible short, strong, gouge-shaped, with rounded, distal edge; body curved and plump; legs vestigial except in the first larval instar (pl. 103 N). Ocelli three in Pachymerinae, one in Bruchinae)

Bruchidae (= *Mylabridae*) (pl. 103 A-N)

- Prementum and mentum without escutcheonlike sclerome. (Labial palpi present, except in a few Haltieinae as *Dibolia* and *Sphaeroderma* (pl. 114 H, and N)) 3
3. Legs present and fully developed; body curved and plump. (Mandible with excavated inner side and single, pointed apex; prementum distinct and covered with an unpaired subtriangular sclerite; mentum distinct, free laterally; labial palpi inserted well apart) ... *Sagridae* (pl. 104 A-H)
 Legs absent; body straight. (Leaf miners with distinct ninth abdominal segment) 4
4. Prementum and mentum not fused; labial palpi inserted well apart at the base of ligula; mandible with excavated inner side and single, pointed apex

Orsodacnidae-Orsodacninae (pl. 105 A-E)

Prementum, mentum, and submentum fused; labial palpi close together; ligula absent; mandible with transverse, approximately gouge-shaped, and slightly scalloped distal edge

Orsodacnidae-Zeugophorinae (pl. 105 F-H)

5. Spiracles of eight abdominal segment biforous, terminal, and projecting like a pair of spurs. (Mentum free laterally and fused posteriorly with submentum; galea and lacinia adapted for sucking of plant juice; larva club-shaped and curved, feeding on submerged parts of fresh-water plants and swamp plants) *Donaciidae* (pl. 106 A-R)
 Spiracles of eighth abdominal segment not projecting like spurs 6

LARVAL FORMS OF COLEOPTERA

6. Labrum small, or indistinct and fused with frons and clypeus.
 (Legs very long, slender, and without pulvillus; abdomen swollen posteriorly, doubled back upon itself, and adapted for carrying a case made either from the excrement of the larva, or, in *Lamprosoma*,⁷⁹ from fine particles of wood glued together with the excrement of the larva and with resin from the host tree) 7
 Labrum well-developed and free 9
7. Tarsungulus short, strongly hamate, with a large heel. (Antenna two-jointed, with conicel sensory appendix (sj pl. 107 G); third joint represented only by a strong seta)
Camptosomatidae - Chlamydinae
 (pl. 107 G, H)
 Tarsungulus slender, somewhat curved and awl-shaped; heel absent or insignificant 8
8. Antenna two-jointed, with a broad, pillbox-shaped sensory appendix (sj pl. 107 A, B); third joint represented only by a seta *Camptosomatidae-Clytrinae* (pl. 107 A-F)
 Antenna three-jointed, with a conicel sensory appendix; third joint seta-bearing and shorter than the appendix. (Frons almost circular in outline and flat)
Camptosomatidae-Cryptocephalinae and *Camptosomatidae-Lamprosominiae*
9. Maxillary palpus three- or four-jointed, excluding palpiger;⁸⁰ eighth abdominal pair of spiracles present and laterally placed; eighth abdominal segment not terminal, its hind margin connected with the front margin of the ninth abdominal segment 10
 Maxillary palpus two-jointed or less; eighth abdominal pair of spiracles either present, but dorsally placed, or absent; eighth abdominal segment terminal with free hind margin 15
10. Tarsungulus long, slender, and without pulvillus; mandible compressed, with two to three distal teeth; epicranial suture long; ocelli absent. (Larva white; abdominal segments without dorsal scleromes and ventrally often with rounded, projecting lobes with many stiff setae)
Eumolpidae (pl. 108 A-M)
 Tarsungulus of moderate length, curved, and usually with pulvillus (pon pl. 109 M); mandible palmate, with four to five distal teeth; combination of a long epicranial suture and lack of ocelli not found 11
- ⁷⁹ The larva of *Lamprosoma bicolor* Kirby and its pointed, hood-shaped case are described by Carlos Moreira (Ann. Soc. Ent. France, vol. 82, 1913, pp. 743-745, one plate).
- ⁸⁰ Very rarely two-jointed, as in *Sphaeroderma* (pl. 114 N).

LARVAL FORMS OF COLEOPTERA

- 11. More than one ocellus on each side of head, usually five or six ocelli; antenna three-jointed 12
One ocellus on each side, or none; antenna two-jointed or less 13
- 12. First eight abdominal segments with a transverse, ventral region with ambulatory warts (pl. 109 G); anal opening dorsal; labial palpus one-jointed. (Spiracles annular or biforous; larva covered with excrement or slimy exudation) ...
Crioceridae (pl. 109 A-G)
First eight abdominal segments without any ambulatory warts; anal opening ventral and placed in the middle of the sucking disk of the tenth abdominal segment; labial palpus two-jointed *Chrysomelidae* (pl. 109 H-M)
- 13. With a combination of the three following characters: Epieranal suture well-developed or long; one ocellus on each side of head; dorsal region of each of first to seventh abdominal segments distinctly subdivided into two or three transverse areas (pl. 110 C and G)
Galerucidae - Galerucinae^{s1} (pl. 110 A-M)
With a different combination of the three characters 14
- 14. Epieranal suture present, but usually short; ocelli absent; dorsal region of each of first to seventh abdominal segments subdivided into three transverse areas. (Intersegmental membranes often large; spiracles annular, except in *Exosoma*, (pl. 111 M), where they are biforous)
Galerucidae - Diabroticinae^{s2}
(*Diabrotica*, *Cerotoma*, *Phyllobrotica*, and *Exosoma lusitanica*) (pl. 111 A-M)
Different combination. (Spiracles always annular)
Galerucidae - Halticinae^{s3} (pls. 112 A-R, 113 A-X, 114 A-O)

^{s1} In the present subfamily Galerucinae are included all of the genera which usually are placed in the subfamily Galerucinae, with the exception of the ones tabulated in the following subfamily, Diabroticinae.

^{s2} This subfamily, which probably includes more genera than the ones listed above, but whose larvae are unknown, is more closely connected with the Halticinae tribes, Crepidoderini, Chaetocnemini, Systemini, and Psylliodini than with the subfamily Galerucinae, as here conceived.

^{s3} The subfamily Halticinae includes genera with remotely related larvae such as *Blepharida*, (112 L, O, Q, R), *Oedionychis* (113 A-E), *Haltica* (112 A, B), *Psylliodes* (112 M, N), and *Sphaeroderma* (114 I-O). When better studied, the classification of the entire family Galerucidae will unquestionably be changed.

LARVAL FORMS OF COLEOPTERA

15. Eighth pair of abdominal spiracles well-developed and dorsal, in some genera biforous, in others annular, eighth abdominal segment terminal, with free hind margin

Hispidae (pl. 115 A-K)

- Eighth pair of abdominal spiracles vestigial; tergum of eighth abdominal segment often provided with an upright fork bearing the cast skins or the excrement of the larva (pl. 116 G) *Cassididae* (pl. 116 A-I)

T. PLATYSTOMOIDEA

KEY TO SUBFAMILIES

1. Legs present, one-, two-, or three-jointed, always without a claw-shaped tarsungular joint. (Spiracles annular, uniforous, or biforous) *Platystomidae - Brachytarsinae* (pl. 117 A-K)

- Legs absent, semiglobular pedal lobes occupying their place. (Mesothoracic spiracle biforous (pl. 117 O, N); abdominal spiracles uniforous; body profusely covered with long hairs) *Platystomidae-Choraginiae* (*Araecerus*) (pl. 117 L-Q)

U. CURCULIONOIDEA

KEY TO FAMILIES AND SUBFAMILIES

1. Mentum-portion of fused subfacial region free laterally; legs present, but small, and usually two-jointed

Brenthidae (pl. 118 A-G)

- Mentum connected laterally with maxillary stipes; legs absent; pedal lobes, occupying their place, often bulging 2

2. Head capsule elongate, broadening posteriorly, and with straight sides. (Head deeply retracted; spiracles uniforous with the mouthpiece equipped with a spoutlike prolongation (pl. 119 A) *Proterhinidae* (pl. 119 A-H)

- Head capsule narrowing posteriorly, and with curved sides ... 3

3. Abdominal hypopleurum subdivided into at least two lobes, one superposed upon the other 7

- Abdominal hypopleurum not subdivided 4

4. Abdominal segments with no more than two transverse, dorsal plicae 5

- Abdominal segments with three or four transverse, dorsal plicae 6

5. More than two ocelli on each side; head retracted; frons indistinct; mentum bearing a median, unpaired plate more or less completely fused with a subtriangular, unpaired plate borne by prementum; labial palpus distinctly two-jointed

Attelabidae - Rhynchitinae and

Attelabidae - Attelabinae (pl. 118 H-M)

LARVAL FORMS OF COLEOPTERA

One ocellus on each side; head protracted; frons distinct; mentum without a plate and prementum without a subtriangular, unpaired plate; basal joint of labial palpus reduced or absent, distal joint distinct

Apionidae (not including *Cylas*)
pl. 120 A-D)

6. Spiracles on second to seventh abdominal segments not projecting and not placed dorsally

Curculionidae and *Scolytidae*^{s4}
(pls. 120 E-G, 121 A-U, 123
A-E)

Spiracles on second to seventh abdominal segments projecting, hook-shaped, and placed dorsally. (Larva submerged, living between the leaves of rice). *Curculionidae - Lissorhoptrinae*

(*Lissorhoptrus simplex*) (pl.
122 A-V)

7. Maxillary palpus two-jointed; spiracles either biforous with large, oval spiracular opening, or, in the single genus *Rhynchophorus*, bilabiate. *Calendridae* (pl. 123 F-H)

Maxillary palpus one-jointed with the dome-shaped, soft end covered with fine, short hairs; spiracles uniforous, with sputlike prolongation from a ring-shaped mouthpiece. (Prothoracic tergum armed in the middle with a transverse ridge composed of a series of ring-shaped scleromes of different sizes) *Platypodidae*^{s5} (pl. 123 I-P)

V. LYMEXYLOIDEA

The systematic position of this series has been discussed in a footnote²⁰. It contains only the one family Lymexylidae which is

^{s4} The larvae of the Curculionidae and Scolytidae can not be separated. In most of the larvae of these two families, the body is whitish, fleshy, subcylindrical, more or less curved, without abdominal prolegs, and not clothed with long hair. However, in the leaf-mining genera *Orchestes* and *Prionomerus*, (pl. 120 E, F), the body is rather straight and either flat both on the dorsal and ventral side, or only flat ventrally but projecting laterally into broad, rounded processes on most of the segments (Trägårdh, Ivar, Arkiv for Zoologi, vol. 6, No. 7, 1910, pp. 1-22, English text, two plates); in the slimy larva of *Cionus solani* Fab. (pl. 120 G), which is free-living on the leaves of *Verbascum*, and in larvae of Hyperini paired prolegs are found on the underside of the abdominal segments; and in the hyperine species *Phelypera distigma* Boheman, from Guatemala, (pl. 121 U), the body is beset on the back with dark hairs as long or considerably longer than the width of the larva.

^{s5} Hubbard, H. G., The Ambrosia Beetles of the United States, U. S. Dept. Agr., Div. Ent., Bul. 7, New Series, 1897, pp. 14-16 with figures.

LARVAL FORMS OF COLEOPTERA

distinguished by the same characters by which the series is defined and in addition by the following characters: Labrum elongate, conical, fitting into a groove on the dorsal side of the mandibles; molar structure of mandible present but rather indistinct; maxillary articulating area well-developed; maxillary palpus three-jointed, palpiger excluded; cardo bipartite; ligula large and broad; prothorax hood-shaped, somewhat swollen dorsally and ventrally; ninth abdominal segment terminal and heavily sclerotized; spiracles bilabiate.

KEY TO SUBFAMILIES

1. Ninth abdominal segment cylindrical, obliquely truncate posteriorly, armed with a raised rim and with rugosities or tubercles on the disk inside of the rim; abdominal epipleural lobes with a hard, tubercled or shagreened surface

Lymexylidae - Lymexylinae
(*Melittomma* and *Atractocerus*) (pl. 124 A-G, J-K, M)

- Ninth abdominal segment elongate conical, thorn-shaped, terminally with upward bent, bicuspidate apex; epipleural lobes glabrous. (First larval instar with a more disklike ninth abdominal segment) *Lymexylidae - Hylecoetinae*
(*Hylecoetus*) (pl. 124 H, L)

^{ss} Modern systematists have divided the family into more than a score of subfamilies on the characters of the adults. Recent studies of the larvae seem to substantiate the correctness of this classification. Much work, however, is still needed before a separation of the larvae into subfamilies and tribes can be established. See: 'St. George, R. A.: "Studies on the larvae of North American beetles of the subfamily Tenebrioninae" . . . (Proc. U. S. Nat.

LARVAL FORMS OF COLEOPTERA

ABBREVIATIONS USED ON THE FIGURES

- 1-10, first to tenth abdominal segments.
a, arm of the spiracular closing apparatus.
abs, annular-biforous type of spiracle (an apparently annular spiracle but provided with two small air-tubes).
ac, accessory ventral condyle of mandible.
al, anal lobe.
alr, alar area (= pase, parascutal area; a tergal area immediately above the epipleural area; in the abdominal segments usually carrying the spiracle).
am, basal articulating membrane of antenna.
amb, ambulatory wart (sometimes named "ampulla" or "scansorial wart").
an, anus.
ans, annular type of spiracle (ringlike with a simple opening and no accessory tubes or chamber).
ant, antenna.
ap, appendage of tenth abdominal segment.
at, atrium of spiracle (a part between the spiracular mouth-piece and the trachea).
b, bulla of spiracle.
bls, bilabiate type of spiracle (an elongate, annular spiracle with a pair of projecting lips interior to the spiracular frame).
bis, biforous type of spiracle (spiracle provided with a pair of distinct airtubes).
c, cardo (with jea, pc, sea; pls. 40 T, 89 G*).
cl, claw (or "ungulus") from distal end of tarsus.
ely, elypterus.
en, canal or sulus in the mandible or in other buccal structures.
eo, membrane between head and prothorax.
col, collar (necklike constriction of head around the occipital foramen).
ers, cribriform spiracle (spiracle provided with a sievelike plate).
ex, coxa.
exl, coxal lobe (= parasternum, an abdominal, usually triangular area extending from hypopleurum toward the sagittal line of sternum; often separating laterally eusternum and sternellum).
da, dorsal articulation of mandible (= mandibular fossa).
dis, dististipes (an anterior portion of the maxillary stipes).
dl, dorso-lateral suture (a frequently rather indistinct groove immediately below the spiracle-bearing parascutal area;

LARVAL FORMS OF COLEOPTERA

- in abdomen parallel with the ventro-lateral suture, in thorax more oblique).
- e, epidermis (=hypodermis).
- ecr, epiceranium.
- ecrs, epicranial suture (median suture between the two epicranial halves and behind the posterior end of frons).
- em, epimeron.
- ep, epistomal margin (the anterior margin of the cranium between the two dorsal articular projections for the mandibular fossae).
- epp, epipleurum (term introduced by Hopkins for the lateral area immediately above the ventro-lateral suture and below the alar area; dorsally limited in thoracic segments by a normally oblique, in abdominal segments always horizontal dorso-lateral suture; pl. 95 Q).
- epr, epipharyngeal rod.
- eps, episternum.
- epx, epipharynx.
- est, eusternum (anterior sternal area in front of the suture between the fureal pits).
- f, frons.
- fe, femur.
- fl, flexor of the mandible.
- fs, frontal suture (paired suture between frons and one or other of epicranial halves; usually dividing the ring-shaped sclerome to which the antenna is attached).
- ga, galea.
- gl, glossa (dorsal surface of ligula).
- gld, gland.
- gs, gular suture (either a paired suture between gular plate and one or other of epicranial halves, or, when pregular plate is present, an unpaired, median longitudinal suture behind this plate and between the ventrally adjacent epicranial halves, or, when the gular area is entirely absent, an unpaired median longitudinal suture behind submentum and between the ventrally adjacent epicranial halves).
- gu, gula (area behind submentum, separated from this by a real or imaginary suture between posterior articulations of the two cardines).
- hb, hypopharyngeal bracoon (a term introduced by A. D. Hopkins for a transverse brace between hypopharynx and the anterior part of the hypostomal margin).
- hc, hypopharyngeal sclerome.
- hp, hypopleurum (a term introduced by A. D. Hopkins for the lateral area immediately below the ventro-lateral

LARVAL FORMS OF COLEOPTERA

- suture; in thorax usually carrying the two scleromes episternum, anterior to the articulation of the coxa, and epimeron, posterior to this articulation).
- hr, hypopharyngeal rod.
- hx, hypopharynx.
- hy, hypostomal margin (the ventral marginal thickening of each of the epieranial halves between the articulation of the ventral mandibular condyle and the ventral tentorial pit, tp; pls. 3 F, 31 F, 99, 107 B).
- is, intersegmental membrane.
- jea, juxtacardo (a separate part of cardo extending from cardo proper toward submentum).
- jx, juxta stipes (a separate part of stipes extending from stipes proper toward mentum).
- lab, labrum.
- lac&la, lacinia.
- lb, labium (the unit consisting of submentum, mentum, prementum, ligula and labial palpi).
- lg, leg.
- li, ligula and in some figures glossa.
- lm, lacinia mandibulae (= prostheca = lacinia mobilis, a fleshy or membranous process from the interior face of the mandible; see: r, retinaculum).
- lp, labial palpus (never more than two-jointed in coleopterous larvae).
- lpg, labial palpiger (in a few coleopterous larvae appearing as a free joint; see: pm, prementum).
- ls, labial stipes (see: pm, prementum).
- lt, median line on the free surface of the airtubes of the biforous spiracle.
- m, mentum (a labial area limited anteriorly by the posterior margin of the premental area and posteriorly by a transverse suture running approximately between the front margins of the maxillary cardines).
- ma, mala (a single maxillary lobe not differentiated into an outer lobe, or galea, and an inner lobe, or lacinia).
- md, mandible.
- mo, the molar or grinding structure of the mandible.
- mpf, maxillary palpiger.
- mst, mesothorax.
- mtt, metathorax.
- mx, maxilla.
- mxl, maxillula (= pgn).
- mxp, maxillary palpus.
- mxs, maxillary articulating area (between stipes maxillae and cardo maxillae, exteriorly, and mentum and submentum, interiorly).

LARVAL FORMS OF COLEOPTERA

- n, nasale (an anterior and median projection from frons, formed either by a fusion of frons, clypeus and labrum, or sometimes by frons and clypeus alone; in this latter case labrum is small and hidden below the nasal projection).
- o, ocellus.
- oe, oesophagus.
- of, occipital foramen.
- or, orifice of the spiracle.
- p, maxillary palpiger.
- pag, paragula (a paired, usually elongate, sclerome on either side of gula; found in ostomid, clerid and some other larvae).
- pase, paraseutal area (= alr, alar area).
- pc, precardo (anterior part of bipartite cardo).
- pg, pregula (an anterior part of the gular plate found in front of a median gular suture; present, for instance, in many hydrophiloid and staphylinoid larvae).
- pgl, paraglossa (paired lobe on either side of glossa (gl); not to be confused with the maxillulae (pgn; pl. 11, fig. E)).
- pgn, maxillula (= superlingua, a single or bidivided, lobe-shaped mouthpart on either side of the hypopharyngeal region).
- ph, pharynx.
- plb, pedal lobe (a fleshy, bumplike, non-segmented rudiment of a leg).
- pm, prementum (= ls plus lpg, term used by K. L. Henrikson for the area lying in front of mentum in coleopterous larvae and consisting of the fused labial stipites with the labial palpigera included but with the ligula and labial palpi excluded).
- po, pleurostomal margin (the lateral marginal thickening of each epieranial half between the dorsal and ventral mandibular articulations).
- pon, paronychial appendix (= pulvillus).
- pos, postscutellum.
- post, poststernellum.
- pr, prostheca (= lm, laeinia mandibulae).
- prt, prothorax.
- pse, prescutum.
- pst, presternum.
- pxs, proxistipes (a posterior portion of maxillary stipes).
- r, retinaculum (a hard, pointed, and tooth shaped process usually near or at the middle of the inner edge of the mandible; never jointed).
- re, retractor mandibulae.

LARVAL FORMS OF COLEOPTERA

- s, seta.
sc, scutum.
sea, subcardo (posterior part of bipartite cardo).
sel, scutellum.
scler, sclerome.
sj, supplementary joint of antenna (= "tactile papilla" or
"sensory appendix").
sm, submentum (an unpaired median area lying approximately
between the maxillary cardines on the underside of the
head).
sp, spiracle.
srp, stridulatory plate.
srt, stridulatory teeth.
st, maxillary stipes.
stl, sternellum.
su, the sucking portion of the last abdominal segment.
sty, stylus.
t, tarsungulus (here regarded as a terminal joint of the leg
formed by fusion of the tarsus and the claw; modern
authors, however, maintain that in coleopterous larvae
with legs having five or less joints this clawlike terminal
structure which they call "pretarsus" or "daetylopodite"
is a simple joint, that there is no claw ("ungu-
lus"), and that tarsus is eliminated or united with tibia).
ta, tentorial arm.
tb, tentorial bridge (bridge within head between the posterior
ends of the hypostomata).
tg, tergum.
ti, tibia.
tp, ventral tentorial pit.
tr, trochanter.
tu, the usually fingershaped, paired airtubes of a biforous
spiracle.
u, uncus.
ur, urogomphus (a process, usually paired, projecting from the
posterior end of tergum of the ninth abdominal segment;
may be jointed and movable by muscles, or unjointed and
immovable; urogomphus is commonly known as "cer-
eus" or "pseudocercus").
vc, ventral condyle of mandible.
vf, fossa in anterior end of hypostoma for the ventral articula-
tion of the mandible.
vl, ventro-lateral suture (or merely the "lateral suture" when
a distinction between this important suture and the
rather insignificant dorso-lateral suture is not necessary;

LARVAL FORMS OF COLEOPTERA

it is a continuous, longitudinal groove, in the thorax running immediately above the two scleromes episternum and epimeron or, when these are indistinct or absent, above the hypopleural area to which they belong, in the abdomen running above hypopleural area and between the pitlike impressions where the ventral and dorsal wedges of the intersegmental membranes meet when these are present).

vr, sensorial wart (= "tuber scansorium" Schiödte).

*, jointlike appendix of galea (= bl, bladelike appendix in Donaciidae; pls. 106 G and K, 110 I, 111 G).

PLATE 20

Histeridae

- A. Platysoma sp. : Right mandible. Dorsal view.
 B. Saprinus estriatus Lee. : Right mandible. Dorsal view.
 C. " " : Head. Dorsal view.
 D. " " : Ventral mouthparts. Ventral view.
 E. Teretrius sp. : Tibia and tarsungulus.
 F. " " : Ventral mouthparts. Ventral view.
 G. " " : Head. Dorsal view.
 H. " " : Right mandible. Dorsal view.
 I. Hololepta yucateca Mars. : Larva. Dorsal view.
 J. " " : Ventral mouthparts with muscles (Diagram).
 K. Paromalus aequalis Say. : Leg.
 L. Hister unicolor L. (Denmark) : Vertical longitudinal section of spiracle, closing apparatus and the epidermal tissues which form these parts in the following larval stage. (Notice the barrel shaped layer of one of the tubes of the next spiracle).
 M. Hololepta yucateca : Thorax. Ventral view.
 N. Hister unicolor : Closing apparatus of spiracle.
 O. " " : Cross section of tubes of biforous spiracle.
 P. " " : Spiraele cut horizontally to show the inner lumen of tubes.
 Q. " " : Spiracle from above.
 R. Hololepta yucateca : Larva. Lateral view.

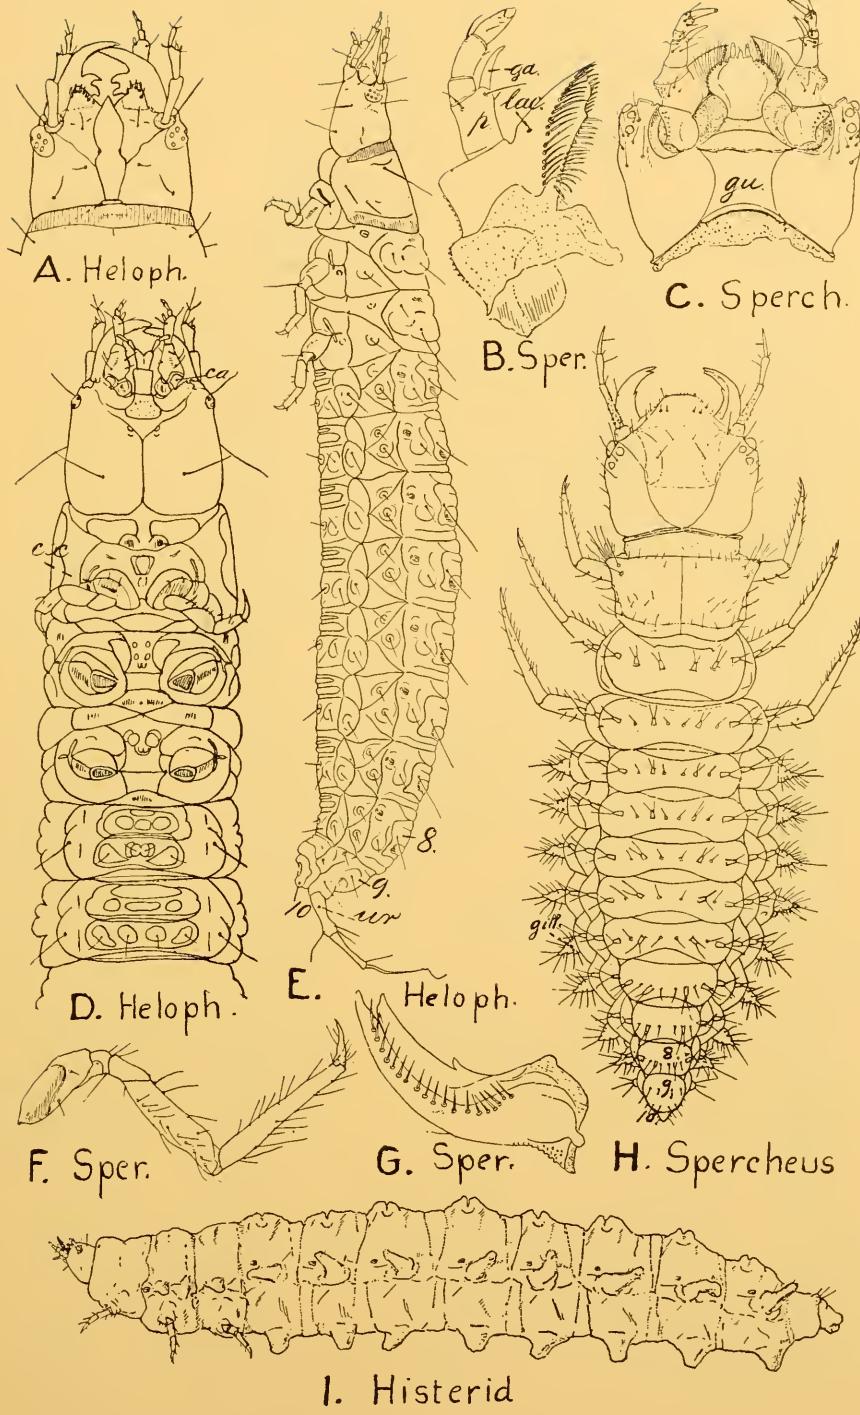

LARVAL FORMS OF COLEOPTERA

PLATE 21

Histeridae, Helophoridae, Spercheidae

- A. *Helophorus aquaticus* L. (Denmark) : Head. Dorsal view.
B. *Spercheus emarginatus* Schall (Denmark) : Maxilla. Ventral view.
C. " " : Head. Ventral view.
D. *Helophorus aquaticus* : Larva. Ventral view.
E. " " : Larva. Ventral view.
F. *Spercheus emarginatus* : Leg.
G. " " : Mandible.
H. " " : Larva. Dorsal view.
I. *Histeridae* (British Guiana. Termitophilous larva of unknown genus collected by Dr. E. A. Emerson) : Larva. Lateral view.

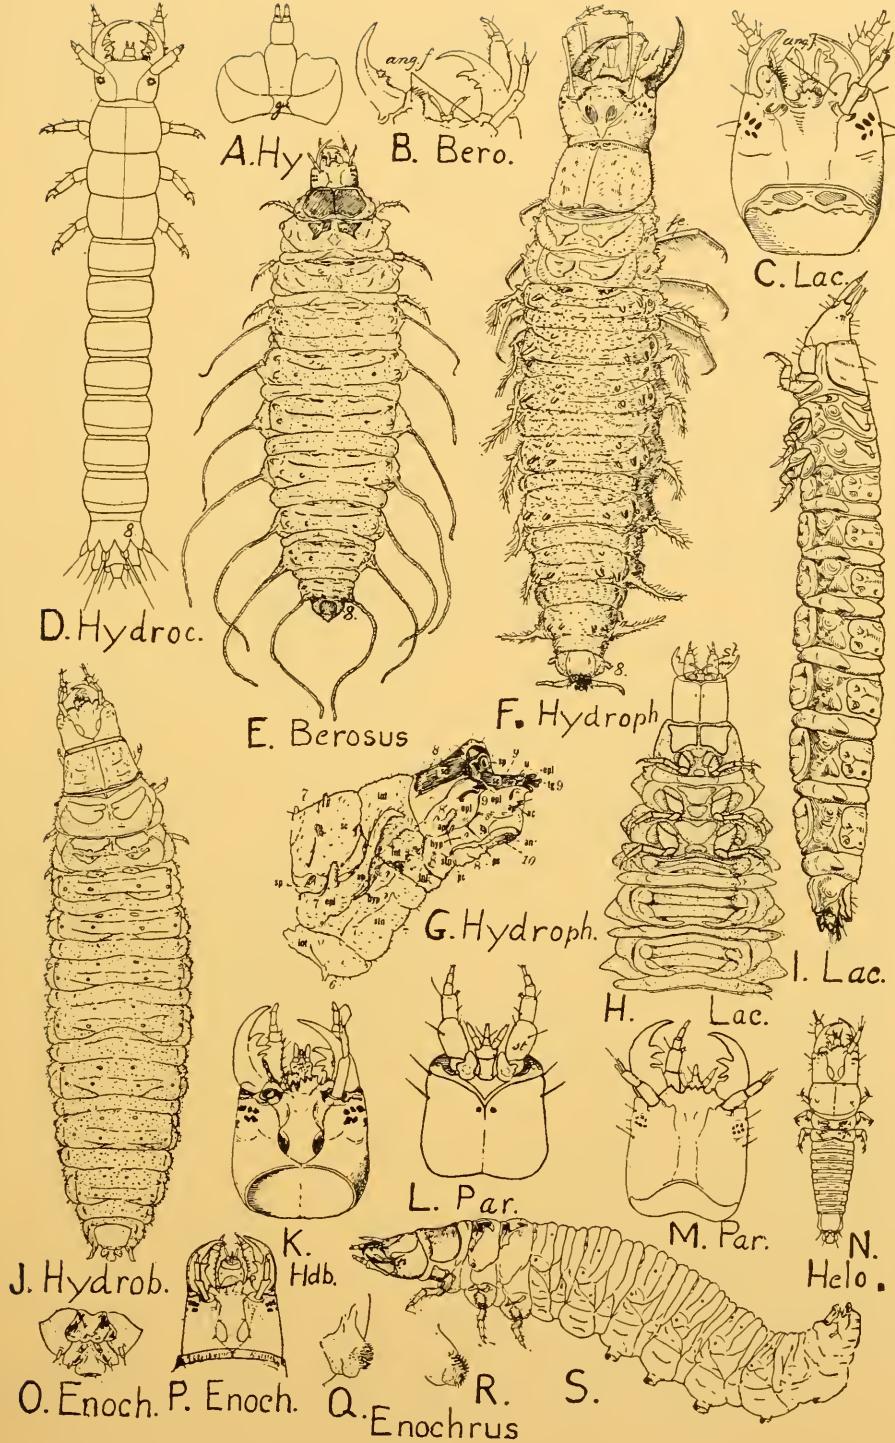

LARVAL FORMS OF COLEOPTERA

PLATE 22

Hydrochidae, Hydrophilidae-Berosinae,

Hydrophilidae-Hydrophilinae, Hydrophilidae-Hydrobiinae

- | | |
|---|--|
| A. <i>Hydrochus squamifer</i> Lee. | : Ventral mouthparts. |
| (After E. A. Richmond) | Ventral view. |
| B. <i>Berosus signaticollis</i> Charp. (Denmark) | : Anterior part of head. Dorsal view. |
| C. <i>Laccobius minutus</i> L. (Denmark) | : Head. Dorsal view. |
| D. <i>Hydrochus squamifer</i>
(After E. A. Richmond) | : Larva. Dorsal view. |
| E. <i>Berosus spinosus</i> Stev. (Denmark) | : Larva. Dorsal view. |
| F. <i>Hydrophilus caraboides</i> L. (Denmark) | : Larva. Dorsal view. |
| G. | : End of body. Lateral view. |
| H. <i>Laccobius minutus</i> | : Anterior part of body. Ventral view. |
| I. " " | : Larva. Lateral view. |
| J. <i>Hydrobius fuscipes</i> L. (Denmark) | : Larva. Dorsal view. |
| K. " " | : Head. Dorsal view. |
| L. <i>Paracymus aeneus</i> Germ. (Denmark) | : Head. Ventral view. |
| M. " " | : Head. Dorsal view. |
| N. <i>Helochares lividus</i> Forster (Denmark) | : First instar. Dorsal view. |
| O. <i>Enochrus melanocephalus</i> Od. (= <i>E. bicolor</i> Payk.) (Denmark) | : End of body. Dorsal view. |
| P. " " | : Head. Dorsal view. |
| Q. " " | : Proleg. Ventro-lateral view. |
| R. <i>Philydrus</i> sp. (Denmark) | : Proleg. Ventro-lateral view. |
| S. <i>Enochrus melanocephalus</i> | : Larva. Dorso-lateral view. |

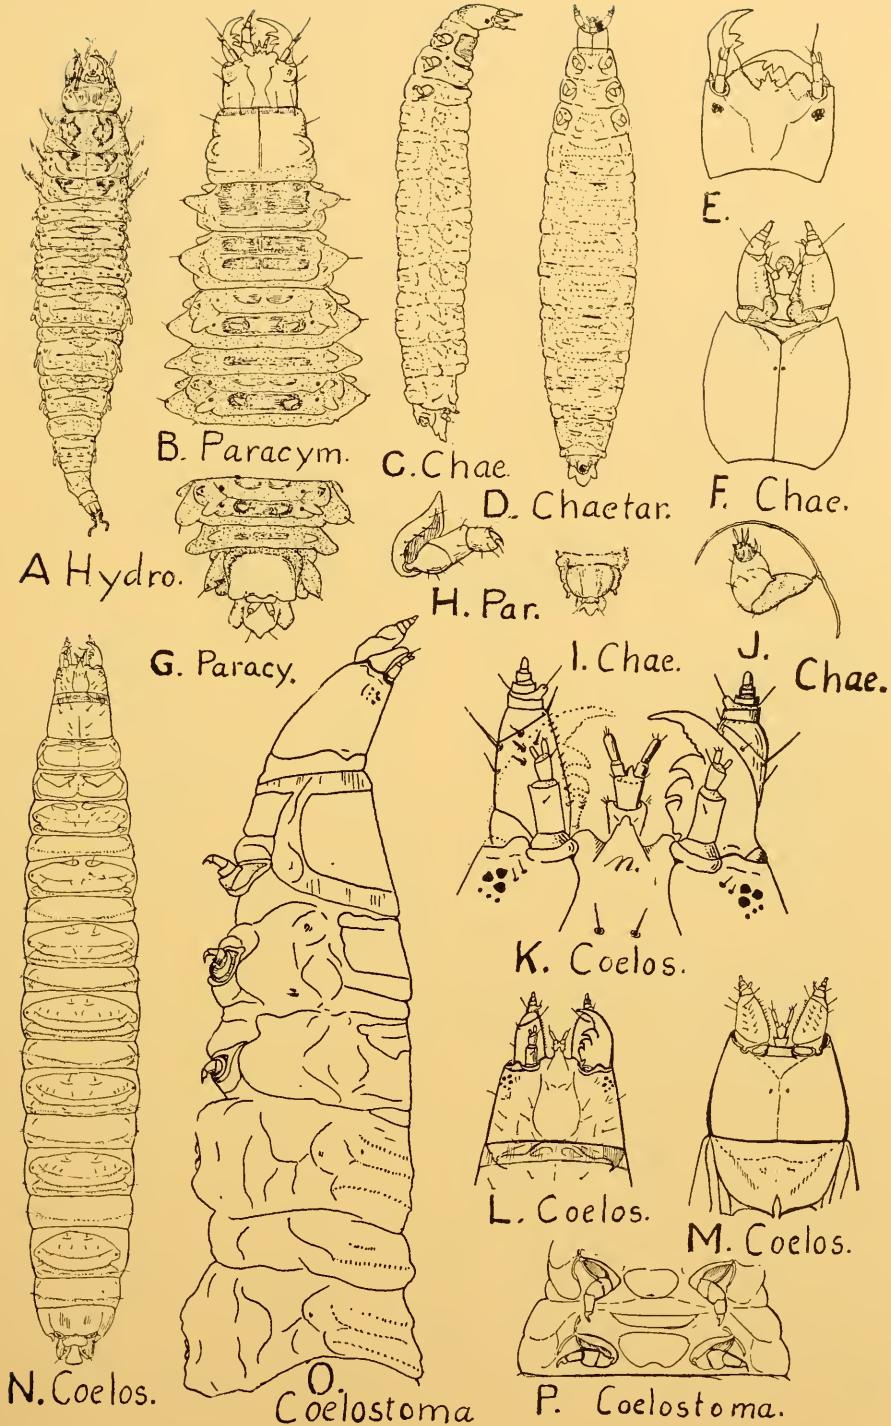

LARVAL FORMS OF COLEOPTERA

PLATE 23

Hydrophilidae-Hydrophilinae (A),
Hydrophilidae-Hydrobiinae (B, G, H),
Hydrophilidae-Sphaeridiinae (C-F, I-P)

- A. *Hydrous piceens* L. (Denmark) : Larva. Dorsal view.
- B. *Paracymus aeneus* Germ. (Denmark) : Anterior part of larva. Dorsal view.
- C. *Chaetartria seminulum* Herbst (Denmark) : Larva. Lateral view.
- D. " " : Larva. Dorsal view.
- E. " " : Head. Dorsal view.
- F. " " : Head. Ventral view.
- G. *Paracymus aeneus* : Posterior part of larva. Dorsal view.
- H. " " : Leg.
- I. *Chaetartria seminulum* : End of body. Dorsal view.
- J. " " : Leg.
- K. *Coelostoma orbiculare* F. (Denmark) : Anterior part of head. Dorsal view.
- L. " " : Head. Dorsal view.
- M. " " : Head. Ventral view.
- N. " " : Larva. Dorsal view.
- O. " " : Anterior part of larva. Lateral view.
- P. " " : Prothorax and mesothorax. Ventral view.

LARVAL FORMS OF COLEOPTERA

PLATE 24.

Hydrophilidae-Sphaeridiinae

- A. Undetermined larva (Cryptopleurum (?), Megasternum (?), or Cercyon (?) 3mm. long) : Left mandible.
(Ireland)
- B. " " : Anterior part of head. Dorsal view.
- C. " " : Right mandible.
- D. " " : Larva. Ventral view.
- E. " " : Ventral mouthparts. Ventral view.
- F. " " : Larva. Dorsal view.
- G. Sphaeridium bipustulatum F. Spiracle of eighth abdominal segment. (Denmark)
- H. " " : Leg.
- I. Undetermined larva (Crypto- pleurum? etc. as above) : Legs and part of abdomen. view.
- J. Sphaeridium bipustulatum : Anterior part of head. Dorsal view.
- K. " " : Maxilla. Ventral view.
- L. Paracercyon flavipes Thunbg. (= Cercyon analis Payk.) : Right mandible.
(Denmark)
- M. Sphaeridium bipustulatum : Larva. Ventral view.
- N. " " : Right mandible.
- O. " " : Left mandible.
- P. Paracercyon flavipes : Left mandible.
- Q. Sphaeridium bipustulatum : End of body. Dorsal view.
- R. Sphaeridium searabaeoides L. : End of body. Dorsal view.
(Denmark)
- S. Sphaeridium bipustulatum : Labium. Ventral view.
- T. Paracercyon flavipes : Larva. Dorsal view.
- U. " " : Ventral mouthparts. Ventral view.

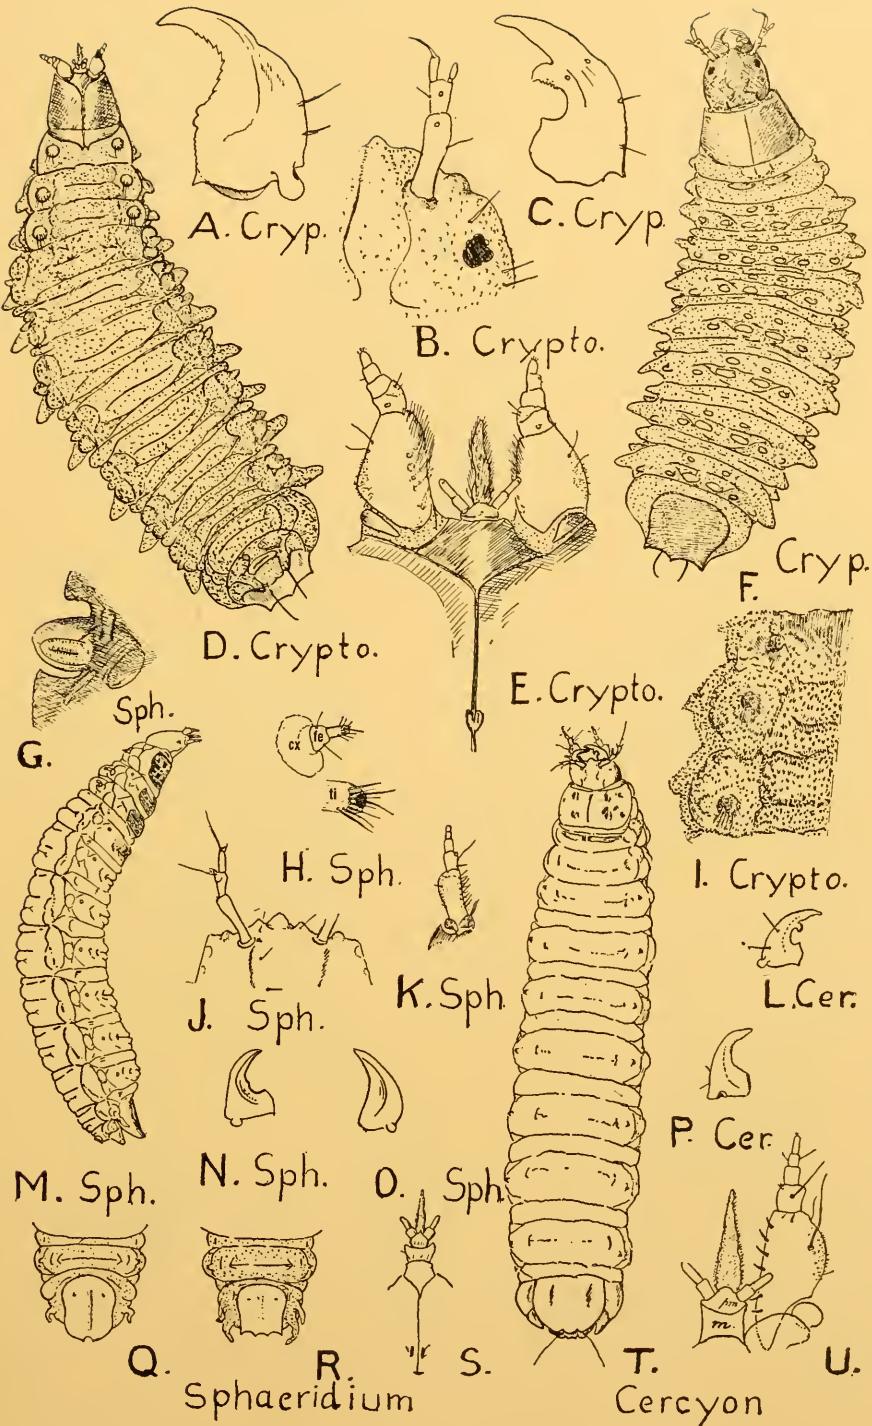

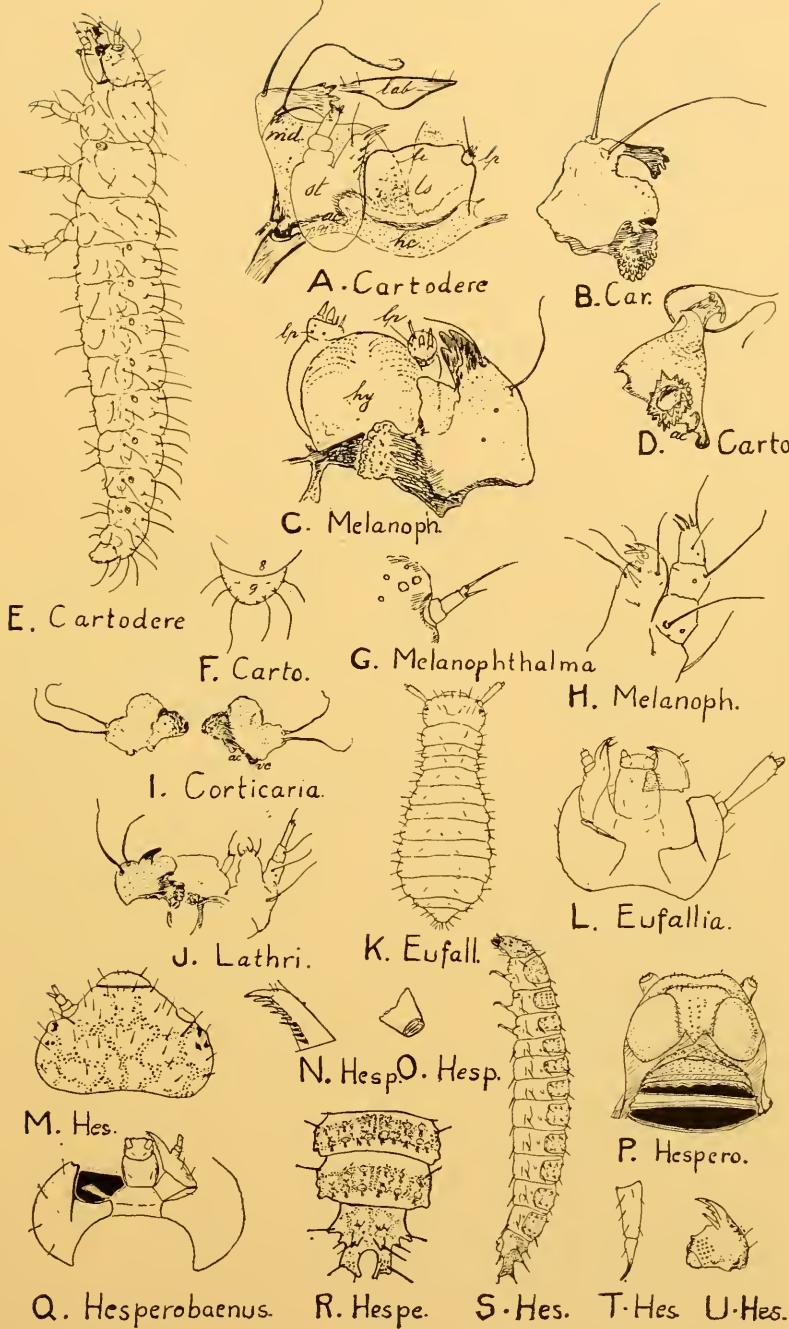

PLATE 25

Lathridiidae, Monotomidae

- A. *Cartodere costulata* Reit. : Anterior part of head.
B. " " : Ventral view.
- C. *Melanophthalma chamaeropis* Fall. : Mandible. Extero-dorsal view.
- D. *Cartodere costulata* : Mandible, labial palpi, hypopharynx.
- E. " " : Mandible. Buccal view.
- F. " " : Larva. Lateral view.
- G. *Melanophthalma chamaeropis* : Eighth and ninth abdominal segments. Dorsal view.
- H. " " : Ocelli, antenna.
- I. *Corticaria dentigera* Lec. : End of maxilla.
- J. *Lathridiidae* (genus?) : Mandible. Ventral view.
- K. *Eufallia seminiveus* Mots. : Mandible. Dorsal view.
- L. " " : Larva. Dorsal view.
- M. *Hesperobaenus* n. sp. (Florida) : Head. Ventral view.
- N. " " : Head. Dorsal view.
- O. " " : Tip of mala.
- P. " " : Spiracle.
- Q. " " : Hypopharynx.
- R. " " : Head. Ventral view.
- S. " " : Seventh, eighth, and ninth abdominal segments. Dorsal view.
- T. " " : Larva. Lateral view.
- U. " " : Tip of leg.
- V. " " : Mandible.

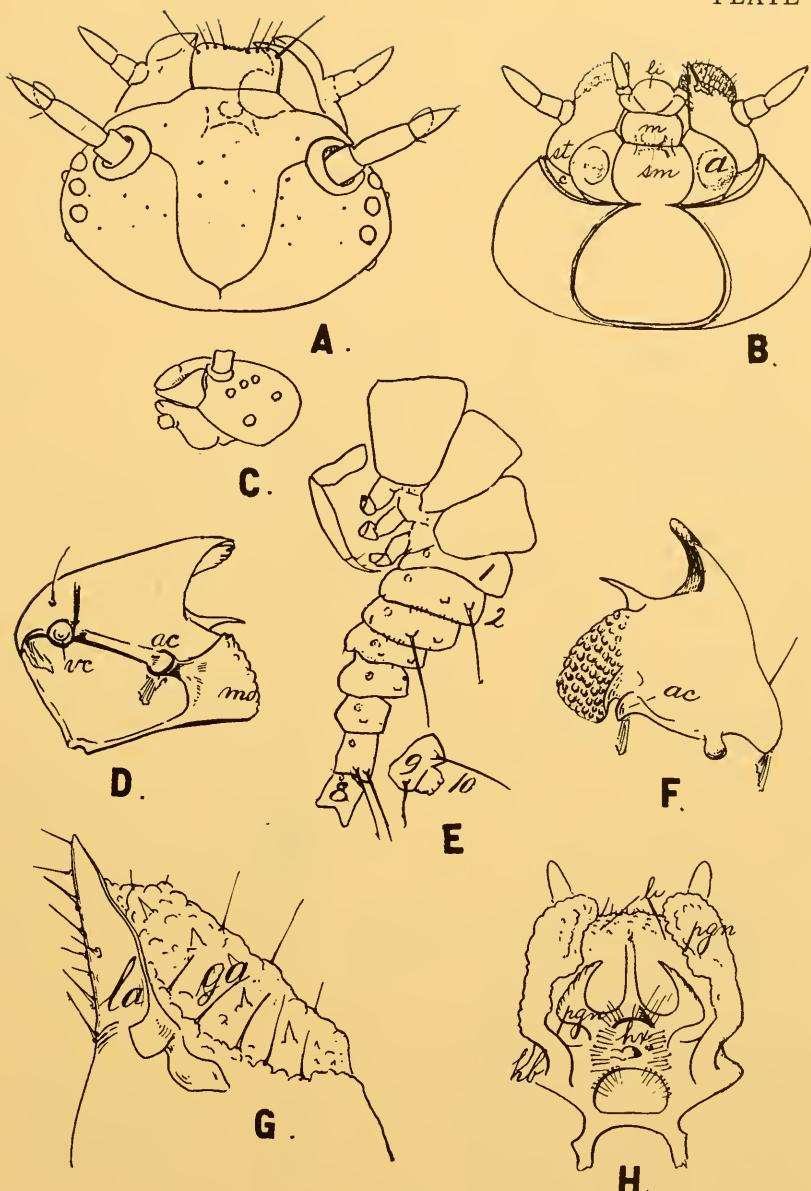

LARVAL FORMS OF COLEOPTERA

PLATE 26

Eucinetidae

- A. Eucinetus (morio Lee.?) (Florida) : Head. Dorsal view.
- B. " " : Head. Ventral view.
- C. " " : Head. Lateral view.
- D. " " : Right mandible. Ventro-basal view.
- E. " " : Larva; notice annular spiracles. (From cast skin on slide). Lateral view.
- F. " " : Left mandible. Ventral view.
- G. " " : Tip of maxilla.
- H. " " : Hypopharynx; pgn to the right, read: pgl.

Euclinetius (morio) Lea?

LARVAL FORMS OF COLEOPTERA

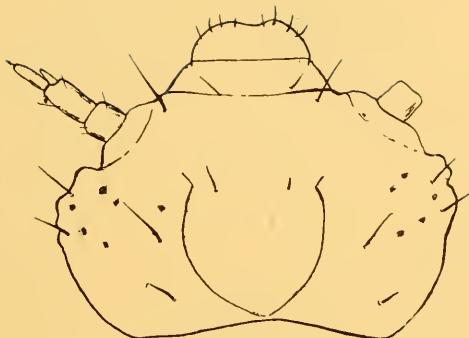

PLATE 27

Derodontidae, Murmidiidae

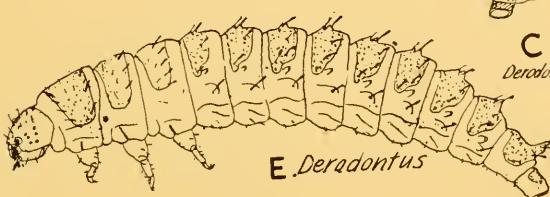

- A. *Derodontus maculatus* Melsh. (?)* : Head. Dorsal view.
B. " " : End of abdomen. Dorsal view.
C. " " : Abdominal biforous spiracle on process.
D. " " : Hypopharynx.
E. " " : Larva. Lateral view.
F. " " : Head. Ventral view.
G. " " : Leg.
H. " " : Left mandible. Ventral view.
I. *Murmidius ovalis* Beck. : Head. Ventral view.
J. " " : Hypopharyngeal structure.
K. " " : Left mandible. Ventral view.
L. " " : Larva. Dorsal view.

* Larva not reared but collected together with imago from slimy fungus below bark of dying tulip tree.

PLATE 28

*Rhizophagidae, Languriidae-Languriinae**Languriidae-Cladoxeninae (K, M, O, Q)*

- A. Rhizophagus grandis Gyll. (Finland) : Head. Ventral view.
 B. " " : Head. Dorsal view.
 C. " " : Ninth abdominal segment. Dorsal view.
 D. " " : Mandible.
 E. " " : Spiracle. Lateral view.
 F. " " : Spiracle. Exterior view.
 G. " " : Larva. Lateral view.
 H. Languria angustata Beauv. : Head. Dorsal view.
 I. " " : Right mandible. Ventral view.
 J. " " : Left mandible. Ventral view.
 K. Pharaxonotha kirschi Reit. : Left mandible. Ventral view.
 L. Languria angustata : Larva. Lateral view.
 M. Pharaxonotha kirschi : Larva. Lateral view.
 N. Languria angustata : Hypopharynx, maxilla.
 O. Pharaxonotha kirschi : Head. Dorsal view.
 P. " " : Larva. Dorsal view.
 Q. " " : Hypopharynx, maxilla.

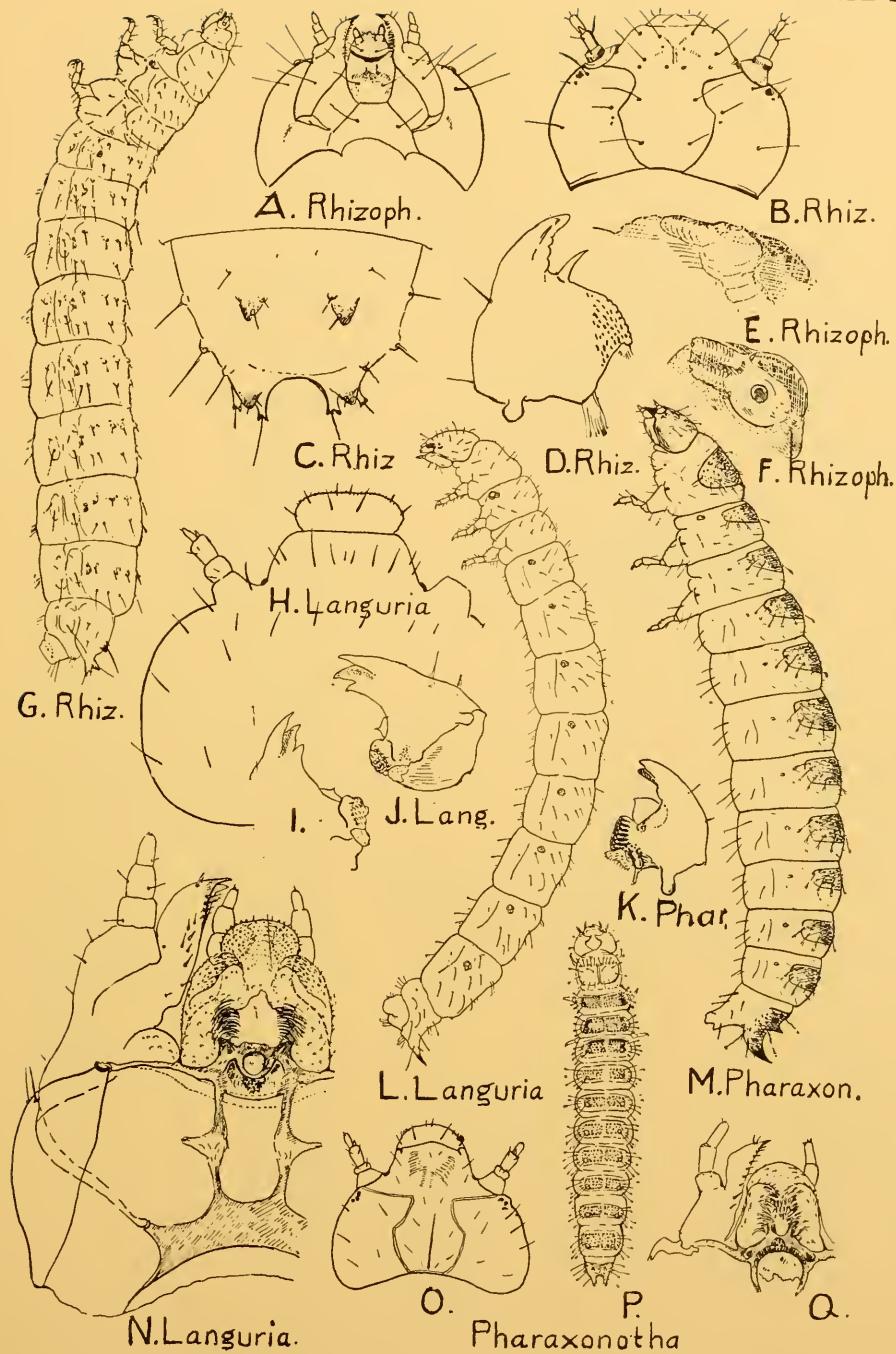

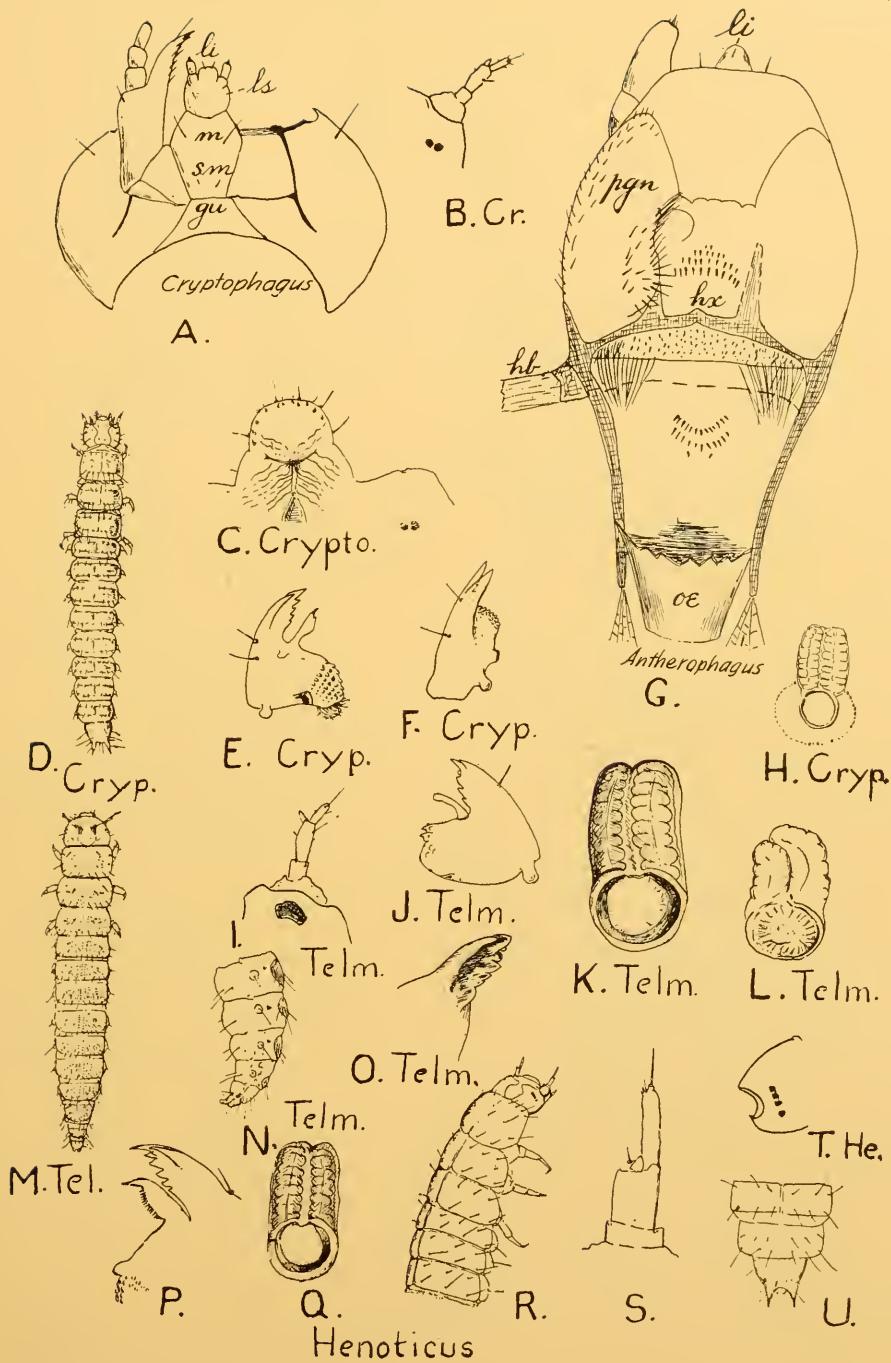

PLATE 29

Cryptophagidae

A.	<i>Cryptophagus saginatus</i> Sturm.	:	Head. Ventral view.
B.	" "	:	Antenna, ocelli. Lateral view.
C.	" "	:	Epipharynx.
D.	" "	:	Larva. Dorsal view.
E.	" "	:	Mandible. Ventral view.
F.	" "	:	Mandible. Exterior view.
G.	<i>Antherophagus</i> sp.	:	Hypopharynx.
H.	<i>Cryptophagus saginatus</i>	:	Spiracle.
I.	<i>Telmatophilus typhae</i> Fall. (Denmark)	:	Antenna, ocellus. Lateral view.
J.	" "	:	Mandible. Ventral view.
K.	" "	:	Thoracic spiraele.
L.	" "	:	Third abdominal spiracle.
M.	" "	:	Larva. Dorsal view.
N.	" "	:	End of abdomen. Lateral view.
O.	" "	:	Tip of mandible.
P.	<i>Henoticus germanicus</i> Reit. (London; in jam)	:	Part of mandible. Ventral view.
Q.	" "	:	Third abdominal spiracle.
R.	" "	:	Anterior part of larva. Dorso-lateral view.
S.	" "	:	Antenna.
T.	" "	:	Ocelli. Lateral view.
U.	" "	:	End of body. Dorsal view.

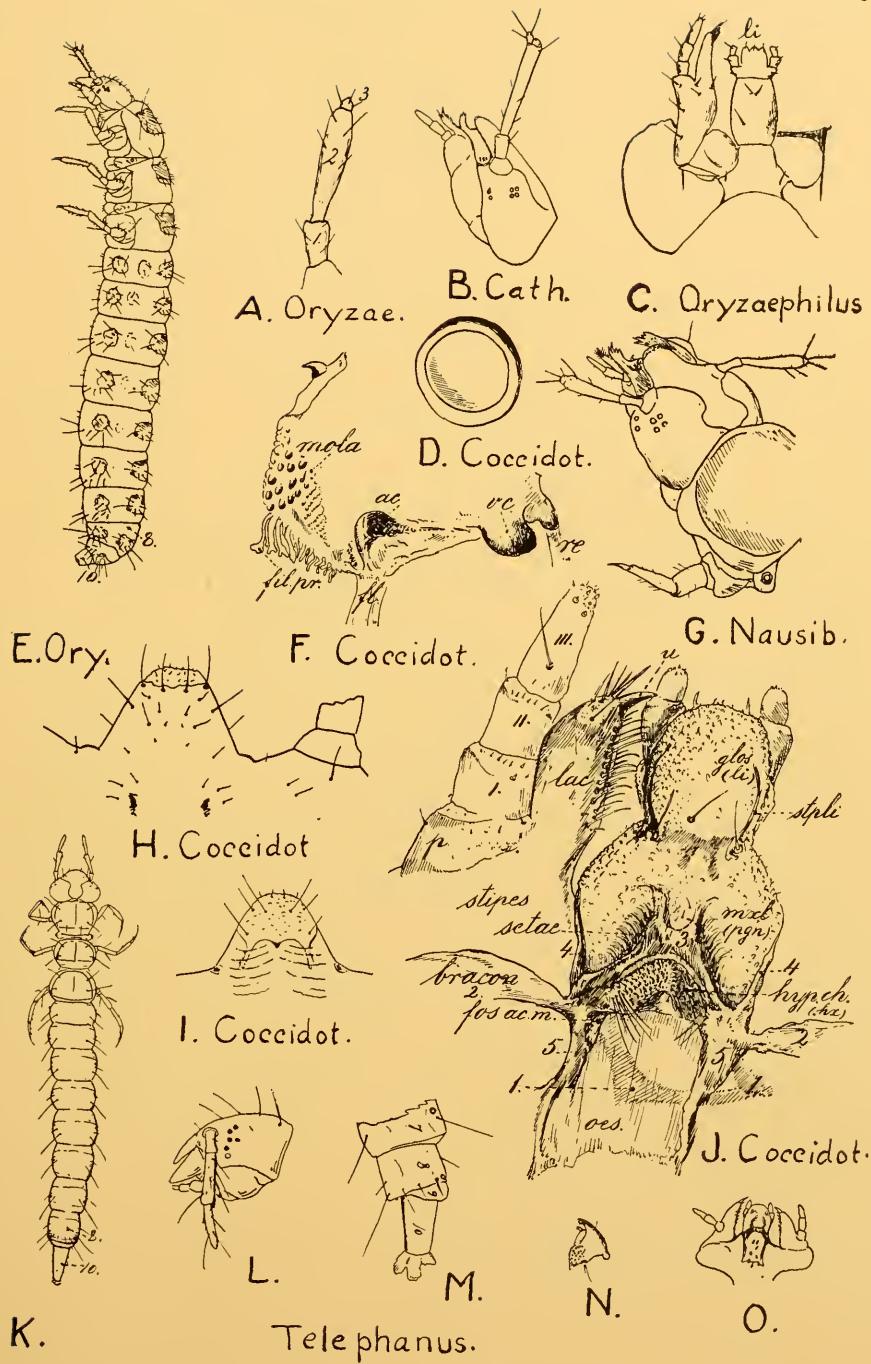

LARVAL FORMS OF COLEOPTERA

PLATE 30

Silvanidae-Silvaninae,
Silvanidae-Telephaninae

- | | |
|--|---|
| A. Oryzaephilus surinamensis L. | : Antenna. |
| B. Cathartus advena Waltl. | : Head. Lateral view. |
| C. Oryzaephilus surinamensis | : Ventral mouthparts.
Ventral view. |
| D. Coccidotrophus socialis Schwarz and
Barber (British Guiana) | : Spiracle. |
| E. Oryzaephilus surinamensis | : Larva. Lateral view. |
| F. Coccidotrophus socialis | : Posterior part of left
mandible; · fil. pr,
stiff chitinous fila-
ments. Ventral view. |
| G. Nausibius clavicornis Kug. | : Head and prothorax.
Dorso-lateral view. |
| H. Coccidotrophus socialis | : Anterior part of head.
Dorsal view. |
| I. " " | : Epipharynx. |
| J. " " | : Maxilla, hypopharynx,
maxillular area and
glossa. (Special ab-
breviations.) |
| K. Telephanus (pallidus Schauf.?) (On
cane, Porto Rico, reared) | : Larva. Dorsal view. |
| L. " " | : Head. Lateral view. |
| M. " " | : End of abdomen. Lat-
eral view. |
| N. " " | : Mandible. |
| O. " " | : Ventral mouthparts.
Buccal view. |

| A. Olibrus aenens F. (Denmark) | : Head. Dorsal view. |
| B. " " | : Mandible. Dorsal view. |
| C. " " | : Leg. |
| D. " " | : Ventral mouthparts. Ven-
tral view. |
| E. " " | : Ocelli. Lateral view. |
| F. " " | : Spiracle. |
| G. " " | : Eighth and ninth abdom-
inal segments. Dorsal
view. |
| H. Laemophloeus biguttatus Say | : Head. Dorsal view. |
| I. " " | : Ventral mouthparts. Ven-
tral view. |
| J. Smicriips palmicola Lec. (Florida) | : Mandible. Ventral view. |
| K. Laemophloeus biguttatus | : Mandible. Dorsal view. |
| L. " " | : Larva; thoracic and ab-
dominal spiracles inset.
Dorsal view. |
| M. Smicriips palmicola | : Larva; annular thoracic
spiracle inset. Lateral
view. |
| N. " " | : Ventral mouthparts. Ven-
tral view. |
| O. " " | : Hypopharyngeal sclerome. |
| P. Laemophloeus biguttatus | : Ninth abdominal segment.
Dorsal view. |
| Q. " " | : End of leg. |

PLATE 32

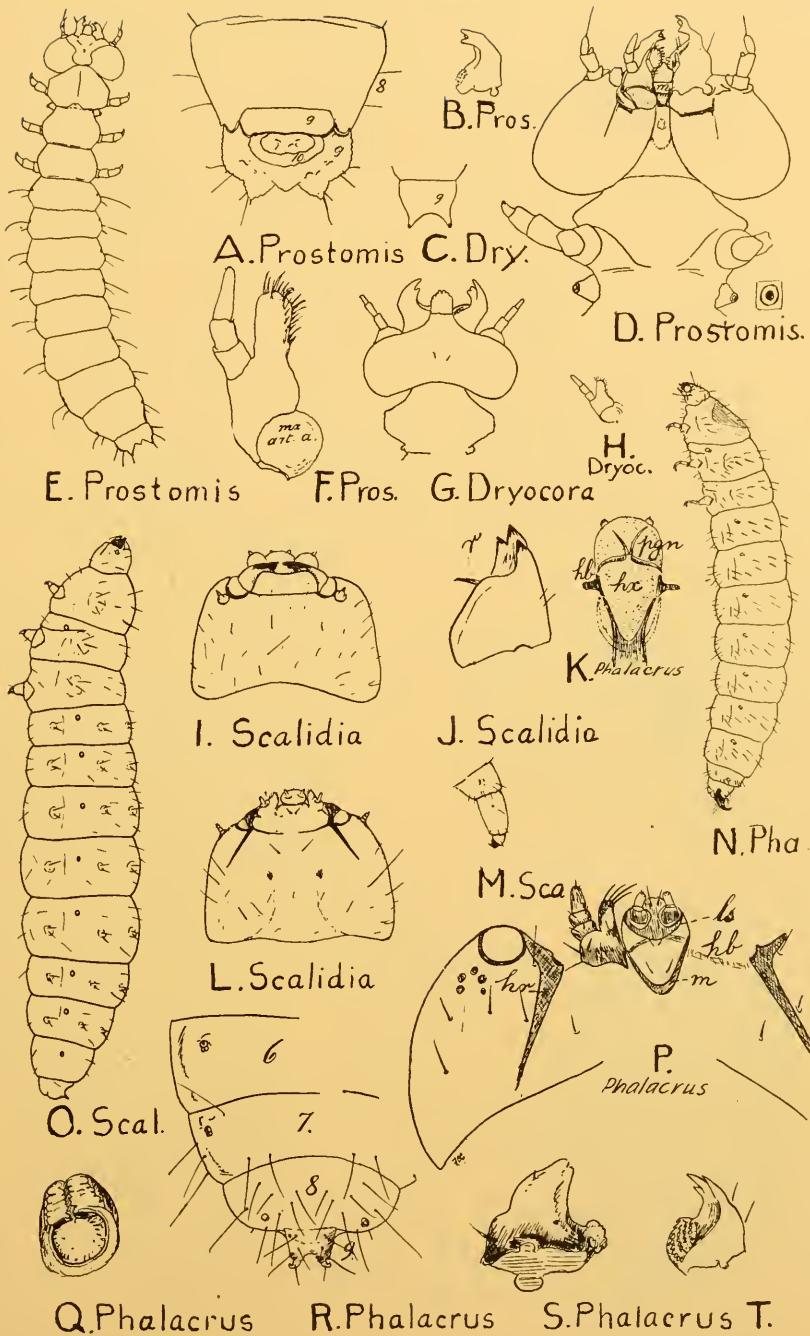

LARVAL FORMS OF COLEOPTERA

PLATE 33

*Prostomidae (A-H),**Catogenidae, Phalacridae*

- A. Prostomis mandibularis F. (Denmark) : End of abdomen. Ventral view.
- B. " " " : Mandible.
- C. Dryocora howitti Pase. (New Zealand) : Ninth abdominal segment. Dorsal view.
- D. Prostomis mandibularis : Head and prothorax; thoracic spiracle inset. Ventral view.
- E. " " " : Larva. Dorsal view.
- F. " " " : Maxilla. Ventral view.
- G. Dryocora howitti : Head and prothorax. Dorsal view.
- H. " " " : Maxilla.
- I. Scalidia linearis Lec. : Head. Dorsal view.
- J. " " " : Mandible. Dorsal view.
- K. Phalaerus sp. : Hypopharyngeal region.
- L. Scalidia linearis : Head. Ventral view.
- M. " " " : Leg.
- N. Phalaerus sp. : Larva. Lateral view.
- O. Scalidia linearis : Larva. Lateral view.
- P. Phalaerus sp. : Head. Ventral view.
- Q. Phalaerus politus Melsh. : Spiracle.
- R. " " " : Sixth to ninth abdominal segments. Dorsal view.
- S. " " " : Mandible. Dorsal view.
- T. Phalaerus sp. : Mandible. Ventral view

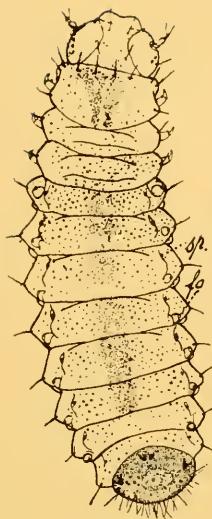

LARVAL FORMS OF COLEOPTERA

PLATE 34

Corylophidae-Arthrolipinae

Corylophidae-Corylophinae

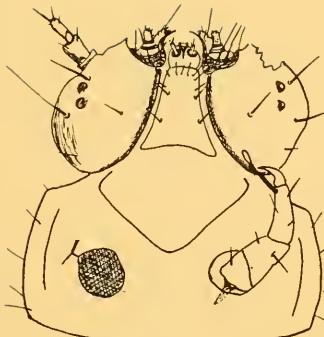

- A. (Arthrolips sp., or possibly: Orthoperus sp.) (?) : Larva; fo, glandular opening or "foramen, Peyerimhoff." Dorsal view.
- B. " " : Mandible.
- C. " " : Head and prothorax. Ventral view.
- D. *Corylophodes marginicollis* Lec. : Head; na, nasale. Ventral view.
- E. *Molamba lunata* Lec. : Head; na, nasale. Ventral view.
- F. *Corylophodes marginicollis* : Larva; fo, foramen. Dorsal view.
- G. *Sacium* sp. : Right side of posterior part of body. Dorsal view.
- H. " " : Leg.
- I. *Molamba lunata* : Larva; fo, foramen. Dorsal view.

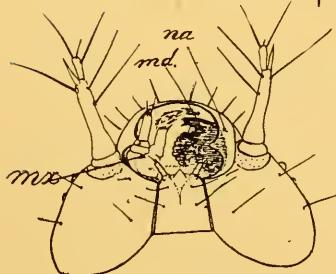

A. Arthrolips

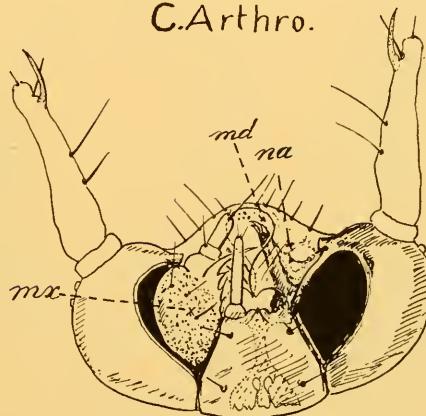

B. Arthro.

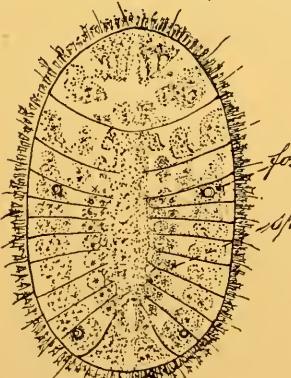

C. Arthro.

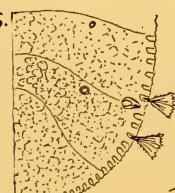

D. Corylophodes.

E. Molamba

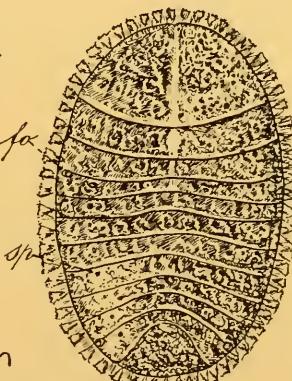

F. Corylophodes

G. Sacium

H. Sacium

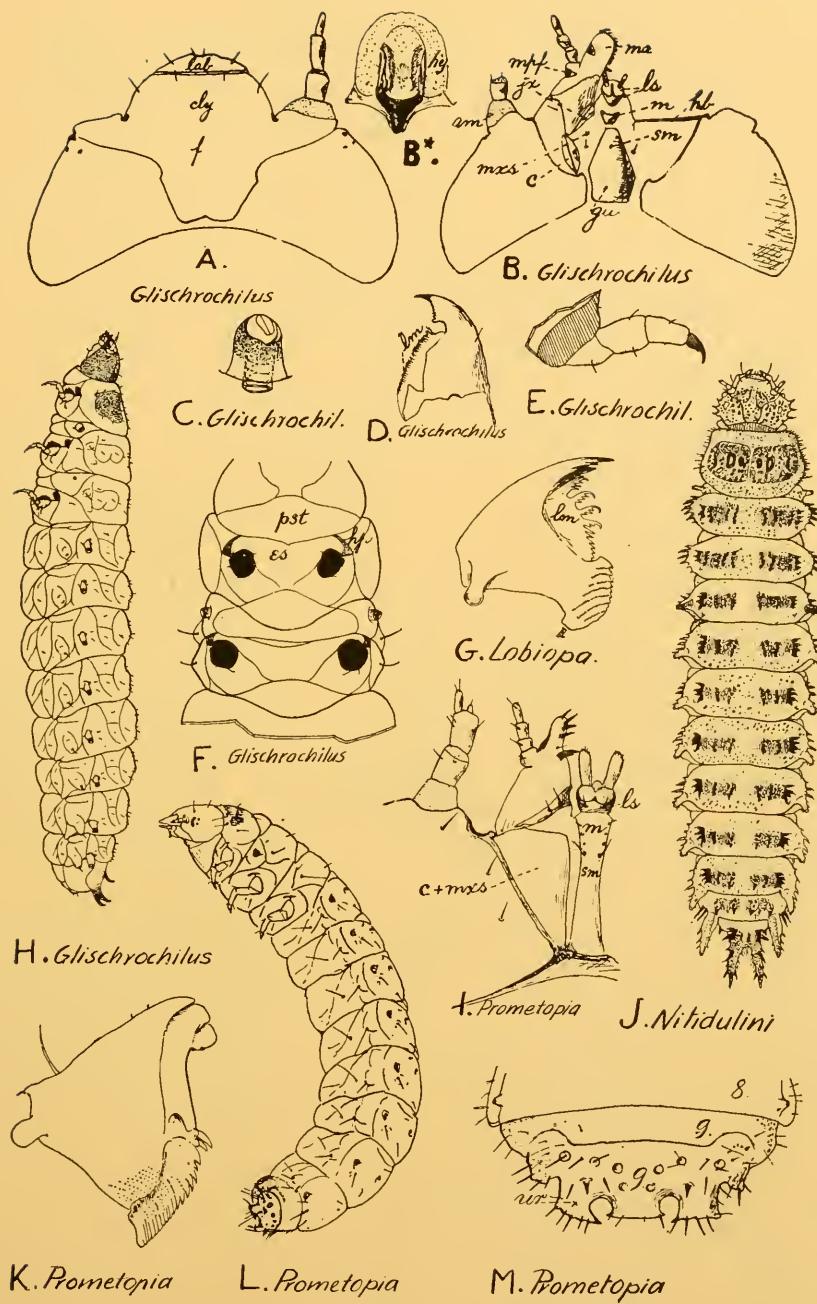

I. Molamba

PLATE 35

Nitidulidae-Nitidulinae,
Nitidulidae-Prometopiinae

- A. *Glischrochilus obtusus* Say : Head. Dorsal view.
- B. " " : Head. Ventral view.
- B.* *Epuraea* sp. : Hypopharyngeal region.
- C. *Glischrochilus obtusus* : Spiraele.
- D. " " : Mandible.
- E. " " : Leg.
- F. " " : Prothorax and mesothorax.
Ventral view.
- G. *Lobiopa insularis* Cast. : Mandible.
- H. *Glischrochilus obtusus* : Larva. Lateral view.
- I. *Prometopia sexmaculata* Say : Antenna and ventral mouth-parts. Ventral view.
- J. Unknown genus near *Epuraea* : Larva. Dorsal view.
- K. *Prometopia sexmaculata* : Mandible (possibly worn apically). Ventral view.
- L. " " : Larva. Mostly a ventro-lateral view.
- M. " " : Ninth abdominal segment. Dorsal view.

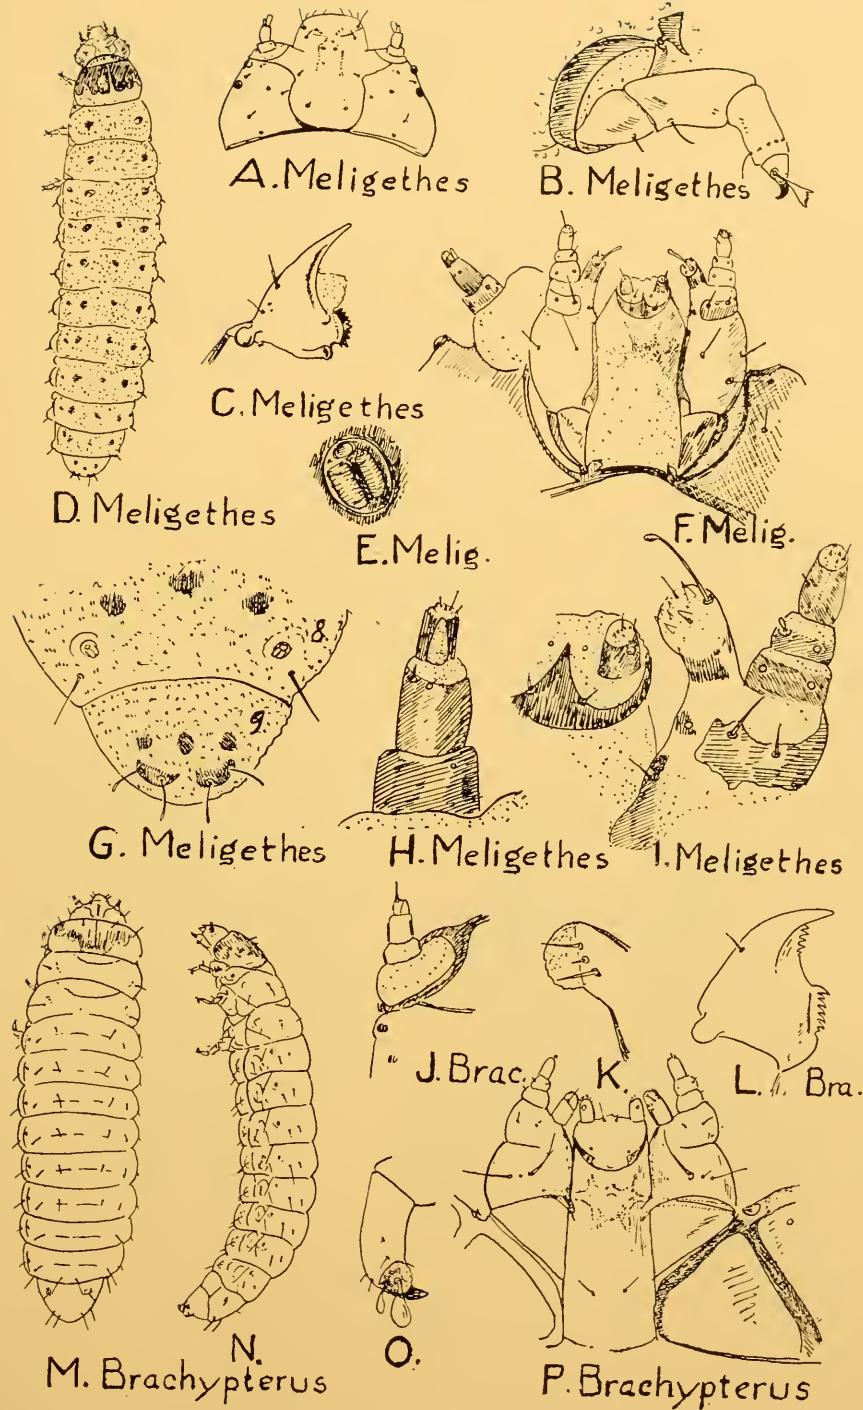

LARVAL FORMS OF COLEOPTERA

LARVAL FORMS OF COLEOPTERA

PLATE 38

Coccinellidae-Coccinellinae,

Coccinellidae-Epilachninae

- A. *Coccinella novemnotata* Hbst. : Spiracle.
- B. " " : Head. Dorsal view.
- C. " " : Buccal structures; diagrammatic. Lateral view.
- D. " " : Mandible. Ventral view. (Compare: Plate 40, fig. B).
- E. " " : Larva. Lateral view.
- F. " " : Tibia and tarsungulus.
- G. " " : Hypopharyngeal bridge and bracon.
- H. " " : Head. Ventral view.
- I. " " : Prothorax and mesothorax. Ventral view.
- J. *Epilachna borealis* F. : Head. Dorsal view.
- K. " " : Larva. Lateral view.
- L. " " : Mandible of first larval instar.
- M. " " : Mandible of last larval instar.
- N. " " : Hypopharynx, maxillulae, and glossa.

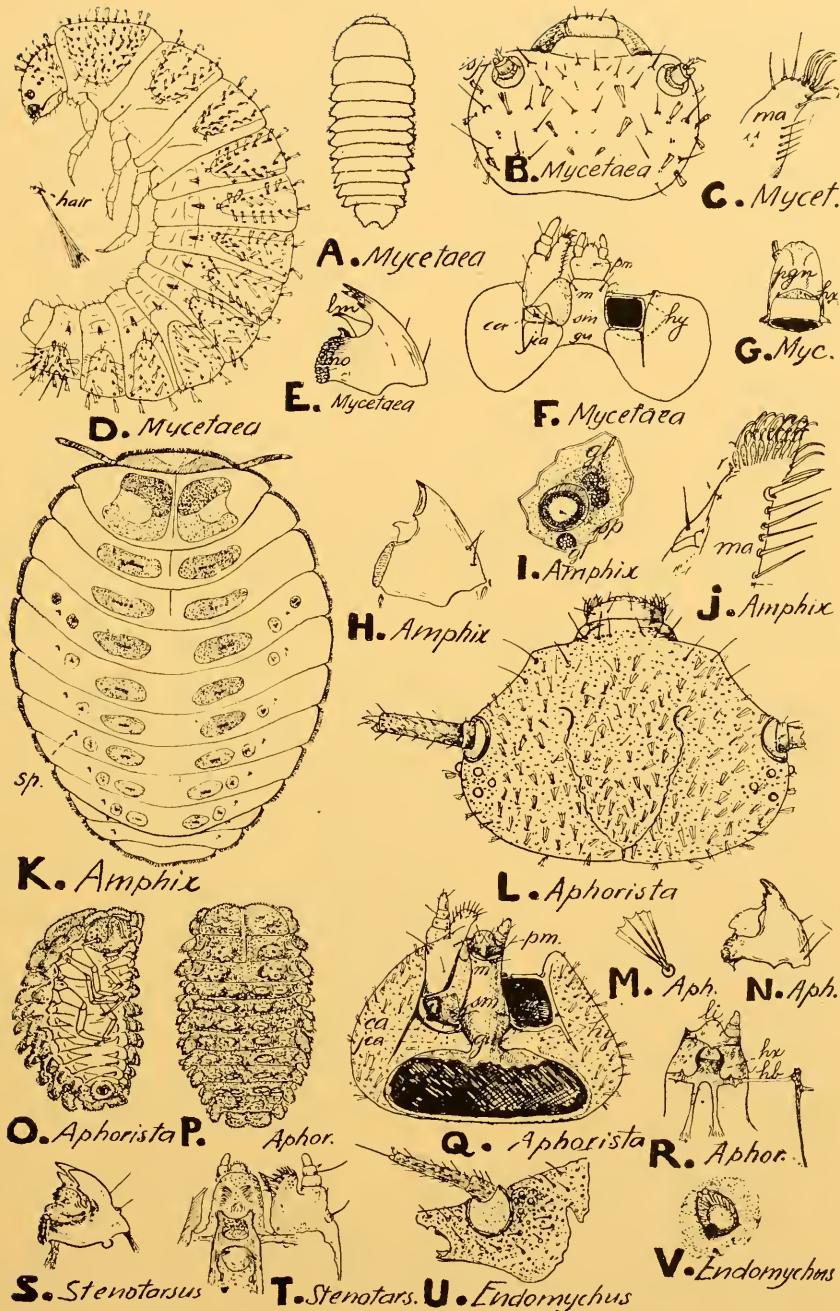

LARVAL FORMS OF COLEOPTERA

PLATE 39

Endomychidae-Mycetacinae (A-G),*Endomychidae-Endomychinae* (H-V)

- A. Mycetaea hirta Marsh. : Outline of larva. Dorsal view.
 B. " " : Head. Dorsal view.
 C. " " : Distal end of maxillary mala.
 D. " " : Larva. Lateral view.
 E. " " : Mandible. Dorsal view.
 F. " " : Head. Ventral view.
 G. " " : Hypopharyngeal structures.
- H. Amphix laevigatus Gerst. (= *Corymalus eastanicolor* Gorham) (Panama) : Mandible. Dorsal view.
 I. " " : Mesothoracic spiracle on ventral side of body.
 J. " " : Distal end of maxillary mala. Ventral view.
 K. " " : Larva. Dorsal view.
 L. Aphorista vittata F. : Head. Dorsal view.
 M. " " : Fan-shaped hair.
 N. " " : Mandible. Dorsal view.
 O. " " : Larva. Ventral view.
 P. " " : Larva. Dorsal view.
 Q. " " : Head. Ventral view.
 R. " " : Hypopharyngeal structures.
- S. Stenotarsus hispidus Hbst. : Mandible. Ventral view.
 T. " " : Hypopharyngeal region.
 U. Endomychus coccineus L. (Denmark) : Lateral part of head.
 V. " biguttatus Say : Spiracle.

LARVAL FORMS OF COLEOPTERA

PLATE 40

Endomychidae-Endomychinae

- A. *Endomychus coccineus* L. (Denmark) : Mandible. Dorsal view.
- B. " " : Hypopharyngeal structures and mandible; mo (?), molar part or possibly irregularly placed accessory ventral condyle (compare: plate 39, figs. E and S, plate 40, fig. J, and also plate 38, fig. D.)
- C. " " : Left and median part of head.
- D. " " : Posterior part of head.
- E. " " : Distal end of maxilla. Ventral view.
- F. " " : Tip of maxillary mala. Dorsal view.
- G. *Lycoperdina ferruginea* Lez. : Head. Dorsal view.
- H. *Lycoperdina succineta* L. (Denmark) : Maxilla and tip of labium.
- I. " " : Hypopharyngeal region and maxillary mala.
- J. " " : Epipharynx and mandible.

- M. " " : Sagittal section of end of abdomen; d, dorsal side; v. ventral side.

Heterocerus

PLATE 65

Helodidae

- A. Prionocyphon discoideus Say. : Mandible and epipharynx; i.s., not branched inner seta of the marginal front row of long epipharyngeal setae.
- A.* Helodes marginata F. (Denmark) : Epipharyngeal marginal setae; i.s., branched inner seta.
- B. Prionocyphon discoideus : Ventral mouthparts and part of prothorax.
- B.* " " : Apical and postapical joints of maxillary palpus; 3, subapical joint; 4, apical joint; spl, sensory papillae; notice the indication of a subdivision of the postapical joint.
- C. " " : Innerside of mouth with large maxillulae.
- D. " " : Tassels of gills.
- E. " " : Larva; aj, multiarticulated apical joint of antenna; sj, supplementary joint of antenna. Lateral view.
- F. " " : Larva; aj and sj as in figure E. Dorsal view.
- G. " " : End of abdomen; AC, alimentary canal with anus; 8 sp, spiracle of eighth abdominal segment. Diagram; lateral view.
H. " " : End of abdomen. Ventral view.

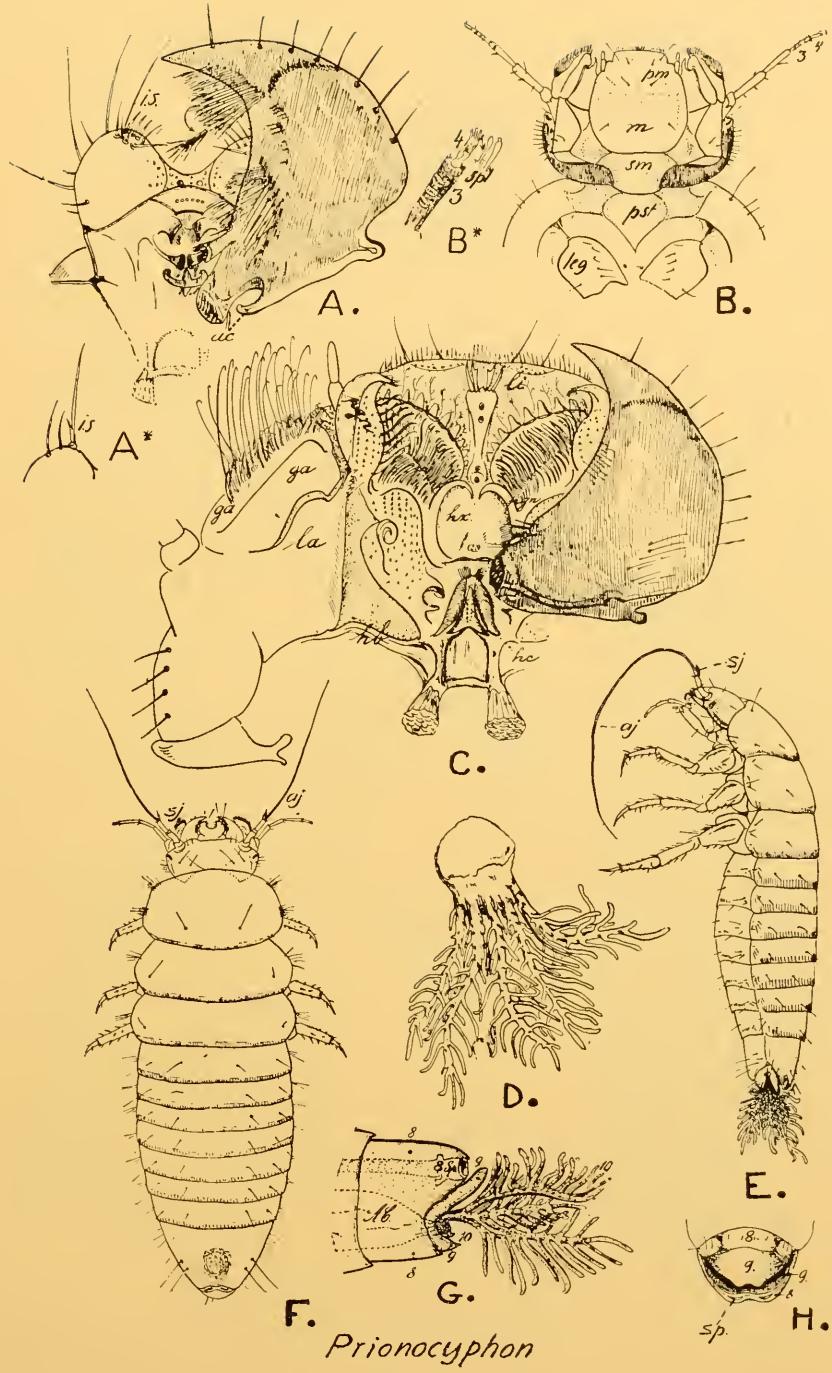

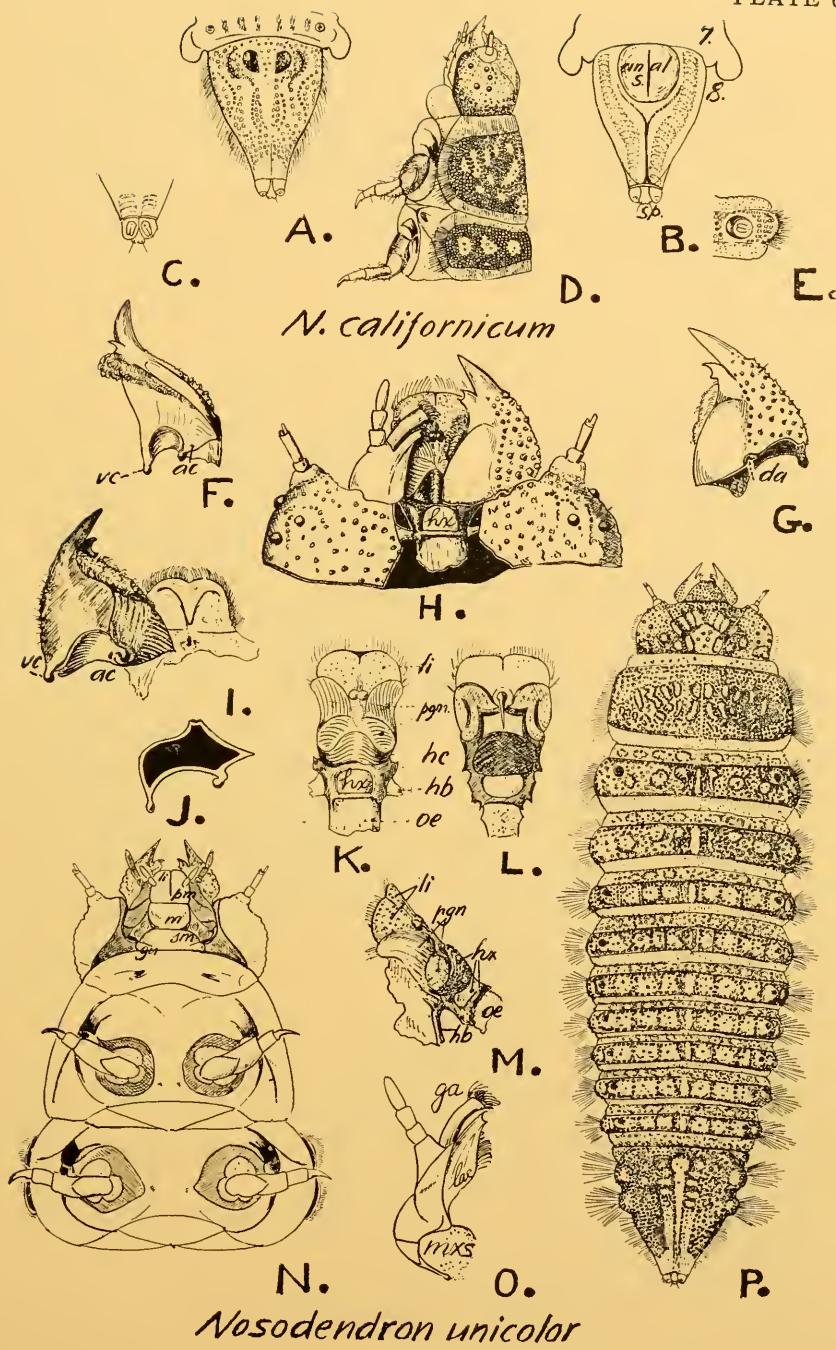

*Prionocyphon*

PLATE 66

Nosodendridae

- A. Nosodendron californicum Horn : End of abdomen. Dorsal view.
 B. " " " : End of abdomen; anal s., anal segment. Ventral view.
 C. " " " : Tip of eighth abdominal segment showing the terminal spiracles. Dorsal view.
 D. " " " : Head, prothorax and mesothorax; notice the position of the mesothorax spiracle as compared with that of *Nosodendron unicolor* on figure P. Lateral view.
 E. " " " : Third abdominal spiracle.
 F. Nosodendron unicolor Say : Right mandible. Oblique view.
 G. " " " : Right mandible. Dorsal view.
 H. " " " : Anterior part of head with buccal roof removed. Dorsal view.
 I. " " " : Epipharynx and ventral surface of mandible.
 J. " " " : Cross-section of base of mandible.
 K. " " " : Glossa, maxillula, and hypopharynx. Dorsal view.
 L. " " " : Inside of the integument of parts shown on figure K.
 M. " " " : Glossa, maxillula, and hypopharynx. Lateral view.
 N. " " " : Head, prothorax, and mesothorax. Ventral view.
 O. " " " : Right maxilla. Ventral view.
 P. " " " : Larva; notice position of mesothoracic spiracle. Dorsal view.

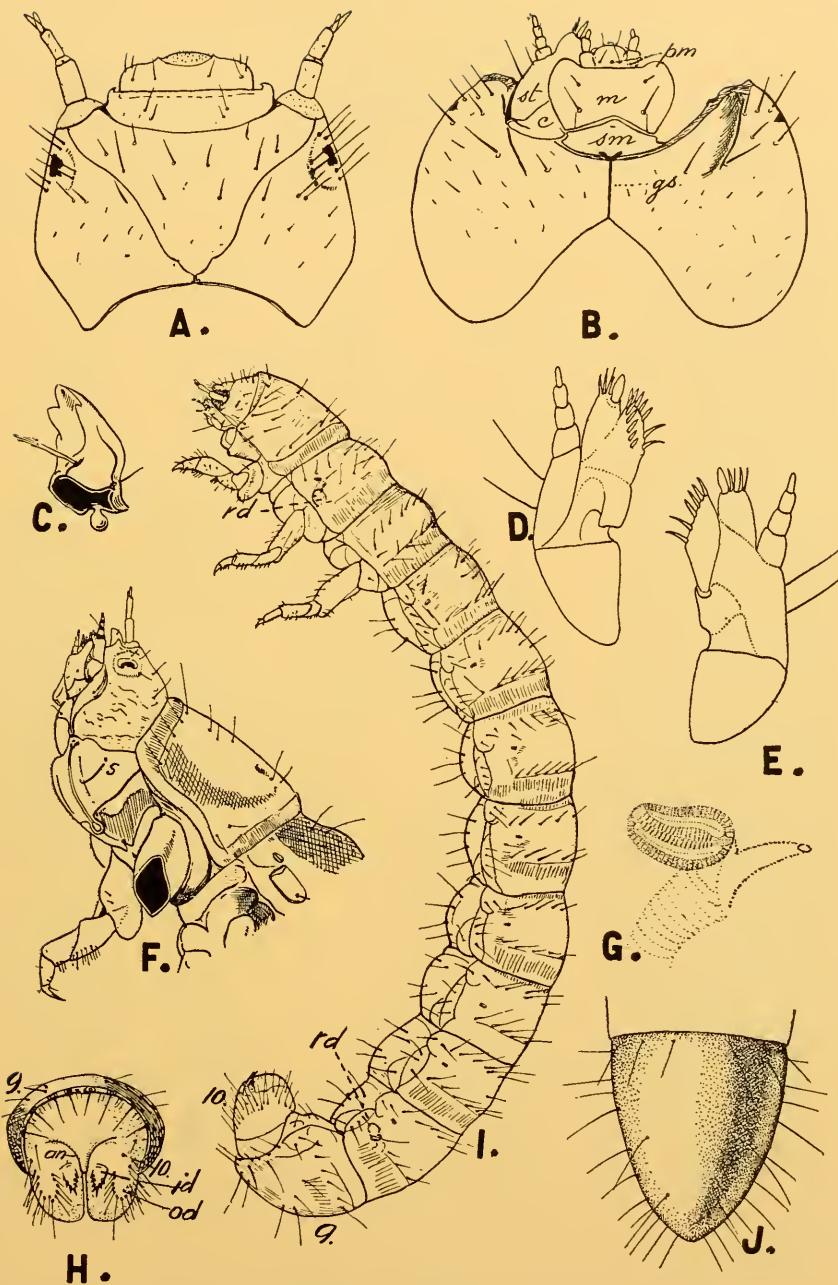

Nosodendron unicolor

PLATE 67

Ptilodactylidae

- A. Ptilodactyla serricollis Say: Head. Dorsal view.
- B. " " : Head. Ventral view.
- C. " " : Right mandible. Dorsal view.
- D. " " : Right maxilla. Dorsal view.
- E. " " : Right maxilla. Ventral view.
- F. " " : Anterior part of larva; j.s, distended jugular skin; note retractile diverticle. Lateral view.
- G. " " : Spiracle.
- H. " " : Tenth abdominal segment; an, anus; id, spinose inner diverticle; od, hairy outer diverticle. Dorsal view.
- I. " " : Larva; rd, retractile diverticle. Lateral view.
- J. " " : Ninth abdominal segment. Dorsal view.

Ptilodactyla

LARVAL FORMS OF COLEOPTERA

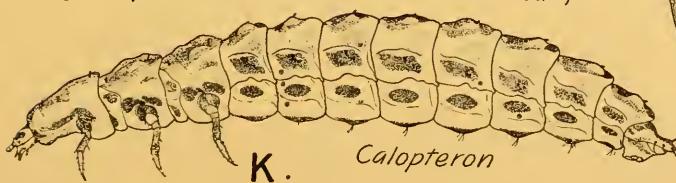

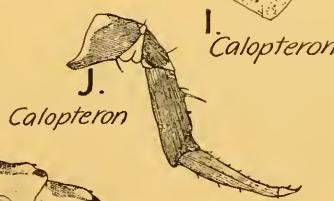

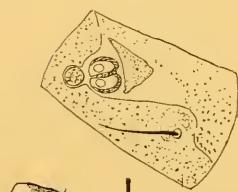

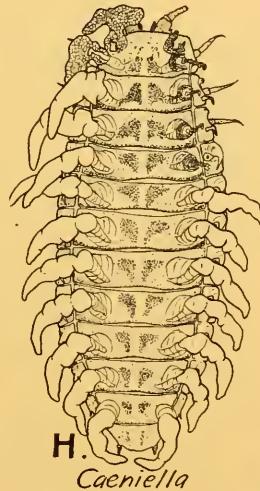

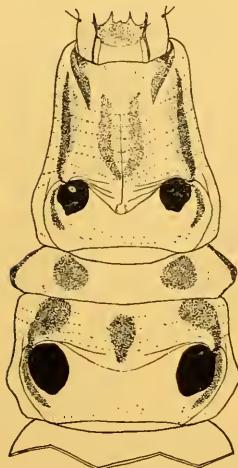

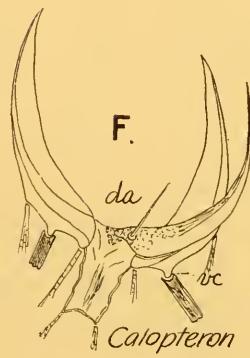

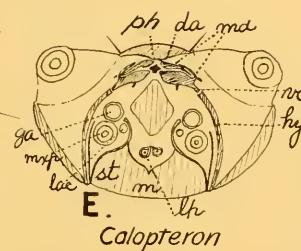

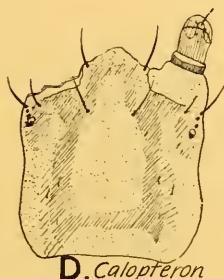

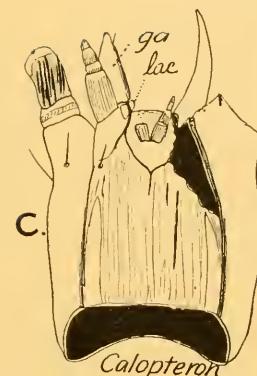

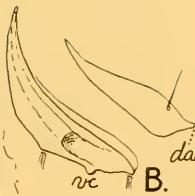

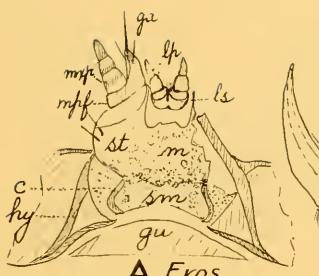

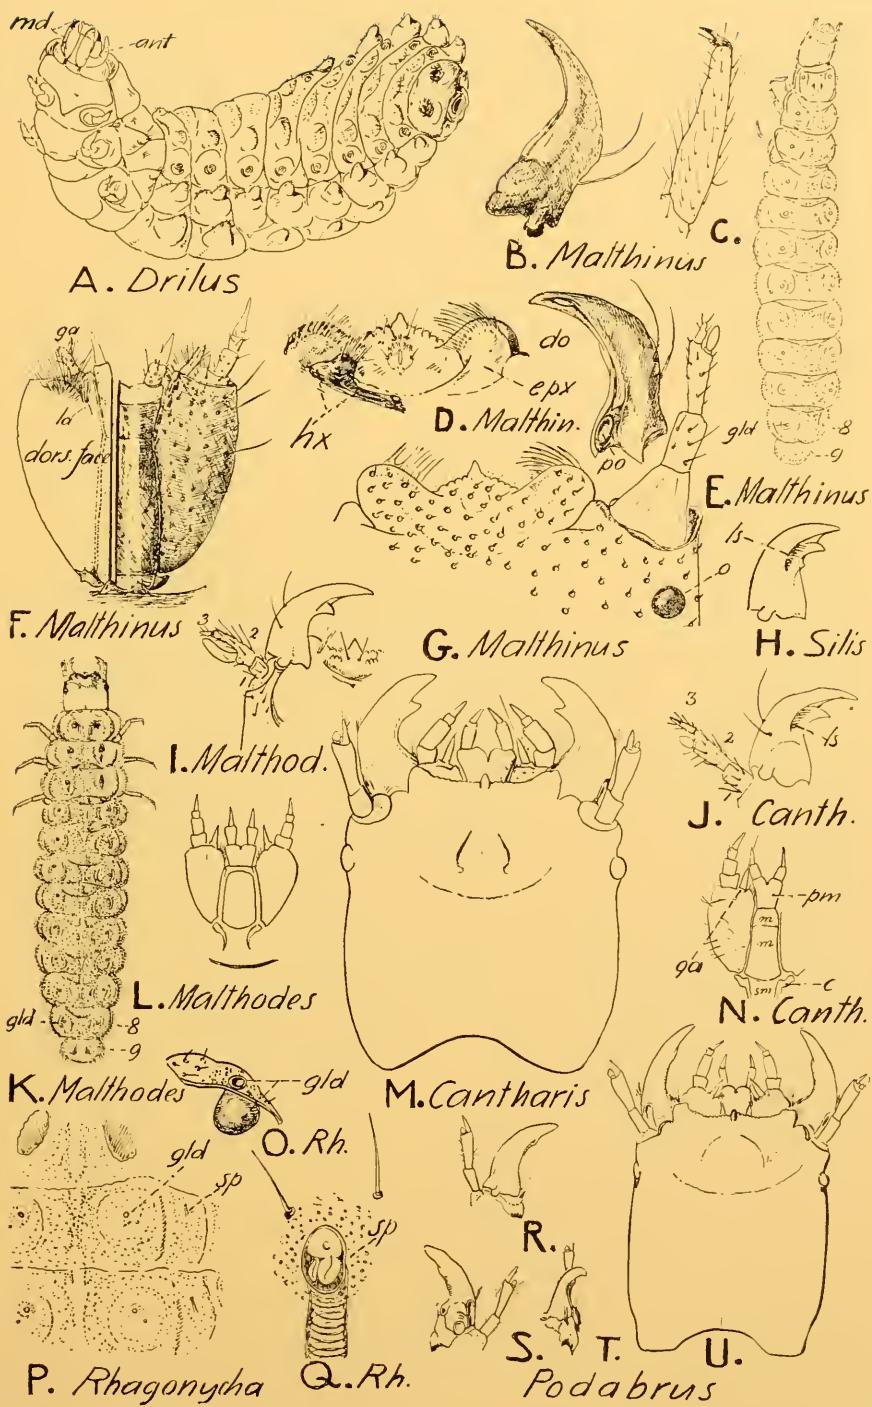

PLATE 77

*Drilidae, Cantharidae-Malthinae.**Cantharidae-Malothodinae, Cantharidae-Cantharinac*

- A. *Drilus concolor* Ahr. (Denmark) : Last larval instar; mandible membranous, except tip. Larva twisted, fitting inside of snail-shell of *Helix*.
- B. *Malthinus flaveolus* Payk. (Germany) : Left mandible. Ventral view.
- C. " " : Tibia and tarsungulus.
- D. " " : Epipharynx and half part of hypopharyngeal sclerome.
- E. " " : Larva. Dorsal view.
- F. " " : Ventral mouthparts. Dorsal view left; ventral view right.
- G. " " : Part of head: do, distal opening of mandibular canal; po. proximal opening.
- H. *Silis nitidula* F. (Europe) : Mandible. ls, longitudinal series of hairs. Ventral view.
- I. *Malthodes marginatus* Latr. (Denmark) : Part of head. Ventral view.
- J. *Cantharis* sp. : Mandible and antenna.
- K. *Malthodes marginatus* : Larva. Dorsal view.
- L. " " : Ventral mouthparts. Ventral view.
- M. *Cantharis* sp. : Outline of head. Dorsal view.
- N. " " : Ventral mouthparts.
- O. *Rhagonycha fulva* Scop. (Denmark) : Dorsal gland.
- P. " " : Metathorax and two abdominal segments. Dorsal view.
- Q. " " : First abdominal spiraele.
- R. *Podabrus tomentosus* Say : Mandible and antenna.
- S. " " : Mandible. Dorsal view.
- T. " " : Mandible. Buccal view.
- U. " " : Outline of head. Dorsal view.

LARVAL FORMS OF COLEOPTERA

PLATE 78

Cantharidae-Chauliognathinae

- A. Chauliognathus scutellaris Lec.: Subnasal region (uncertain whether labrum or epipharynx); snl, subnasal lobe; snsc, subnasal sclerite.
- B. " " : Mesothoracic spiracle; so, spiracular opening furnished with marginal hairs; tb, possibly the reduced airtubes.
- C. " " : Anterior part of head; n, nasale; snl, subnasal lobe. Dorsal view.
- D. " " : Larva. Dorsal view.
- E. " " : Head opened; hx, hypopharyngeal middle area with dark median triangular spot; hy, hypostome; sh, straining hairs from maxillulae. Dorsal view.
- F. " " : Larva. Ventro-lateral view.
- G. " " : Mandible; ed, main conduit for juice; ls, lateral series of fine hairs. Buccal view.
- H. " " : Underside of head; ventral mouthparts drawn back.
- H.* " " : Tip of antenna.
- I. " " : Underside of head; ventral mouthparts drawn forth; snbf, s, subfacial sinus.

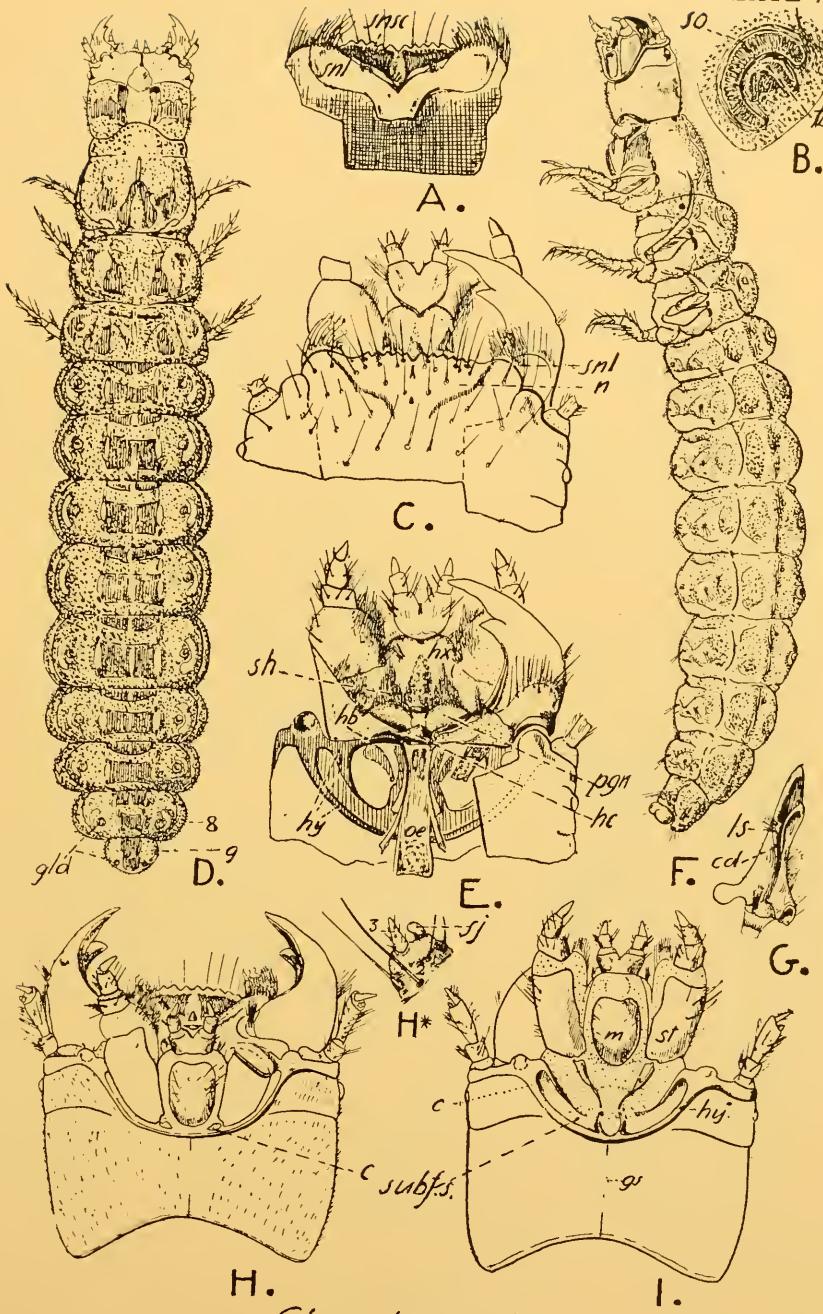

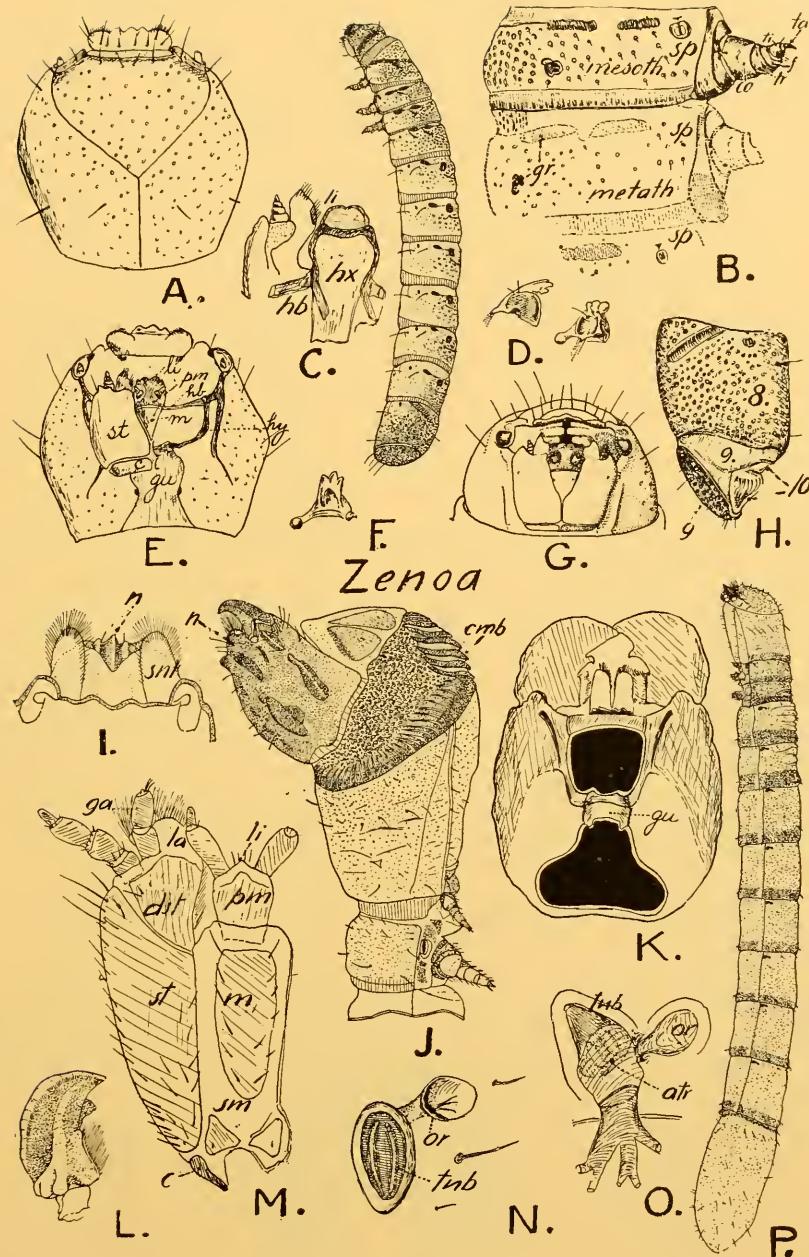

*Chauliognathus*

PLATE 79

Rhipiceridae, Cebrionidae

- A. *Zenoa piecea* Beauv. : Head. Dorsal view.
 B. " " : Mesothorax, metathorax, and part
 of first abdominal segment; gr,
 groove. Lateral view.
 C. " " : Ligula, hypopharynx and part of
 maxilla. Dorsal view.
 D. " " : Left mandibles. Lateral view and
 exterior view.
 E. " " : Head. Ventral view.
 F. " " : Right mandible. Buccal view.
 G. " " : Head. Ventro-frontal view.
 H. " " : End of abdomen. Lateral view.
 I. *Cebrio antennatus* Schfr. : Nasal region; snl, subnasal lobe.
 Ventral view.
 J. " " : Head, prothorax, and mesothorax;
 cmb, cervical membrane expanded.
 Lateral view.
 K. " " : Head. Ventral view.
 L. " " : Right mandible. Ventral view.
 M. " " : Maxilla and labial parts; dst, dis-
 tistipes. Ventral view.
 N. " " : Abdominal spiracle; or, spiracular
 opening; tub, airtubes. Exterior
 view.
 O. " " : Abdominal spiraele; atr, atrium; or,
 opening; tub, airtube. Interior
 view.
 P. " " : Larva. Lateral view.

*Ostomidae-Tenebroidinae,**Ostomidae-Ostominae (D)*

- A. *Airora cylindrica* Serv. : Left mandible; without lacinia mandibulae. Dorsal view.
- B. *Corticotomus cylindricus* Lec. : Right mandible; lni, lacinia mandibulae. Ventral view.
- C. *Airora cylindrica* : Part of head with ocellar group and antenna. Lateral view.
- D. *Ostoma ferrugineum* L. (Canada) : Larva. Dorso-lateral view.
- E. *Corticotomus cylindricus* : Larva; pst, presternal plate; stpl, sternal plate.
- F. *Airora cylindrica* : Larva. Dorso-lateral view.
- G. " " : Head and prothorax; pst, presternal plate; stpl, sternal plate; sp, annular spiracle.
- H. *Corticotomus cylindricus* : Ninth abdominal segment with paired urogomphi.
- I. *Temnochila virescens* F. : Ninth abdominal segment with one of the two urogomphi. Lateral view.
- J. " " : Left mandible. Ventral view.
- K. " " : Dorsal (d) and ventral (v) sclerites of thoracic segments.
- L. " " : Biforous spiracle.
- M. " " : Biforous spiracle and closing apparatus.
- N. " " : Closing apparatus.
- O. *Tenebroides nanus* Melsh. : Ninth abdominal segment with one of the two urogomphi. Lateral view.
- P. " " : Right mandible. Dorsal view.
- Q. " " : Dorsal (d) and ventral (v) sclerites of thoracic segments.

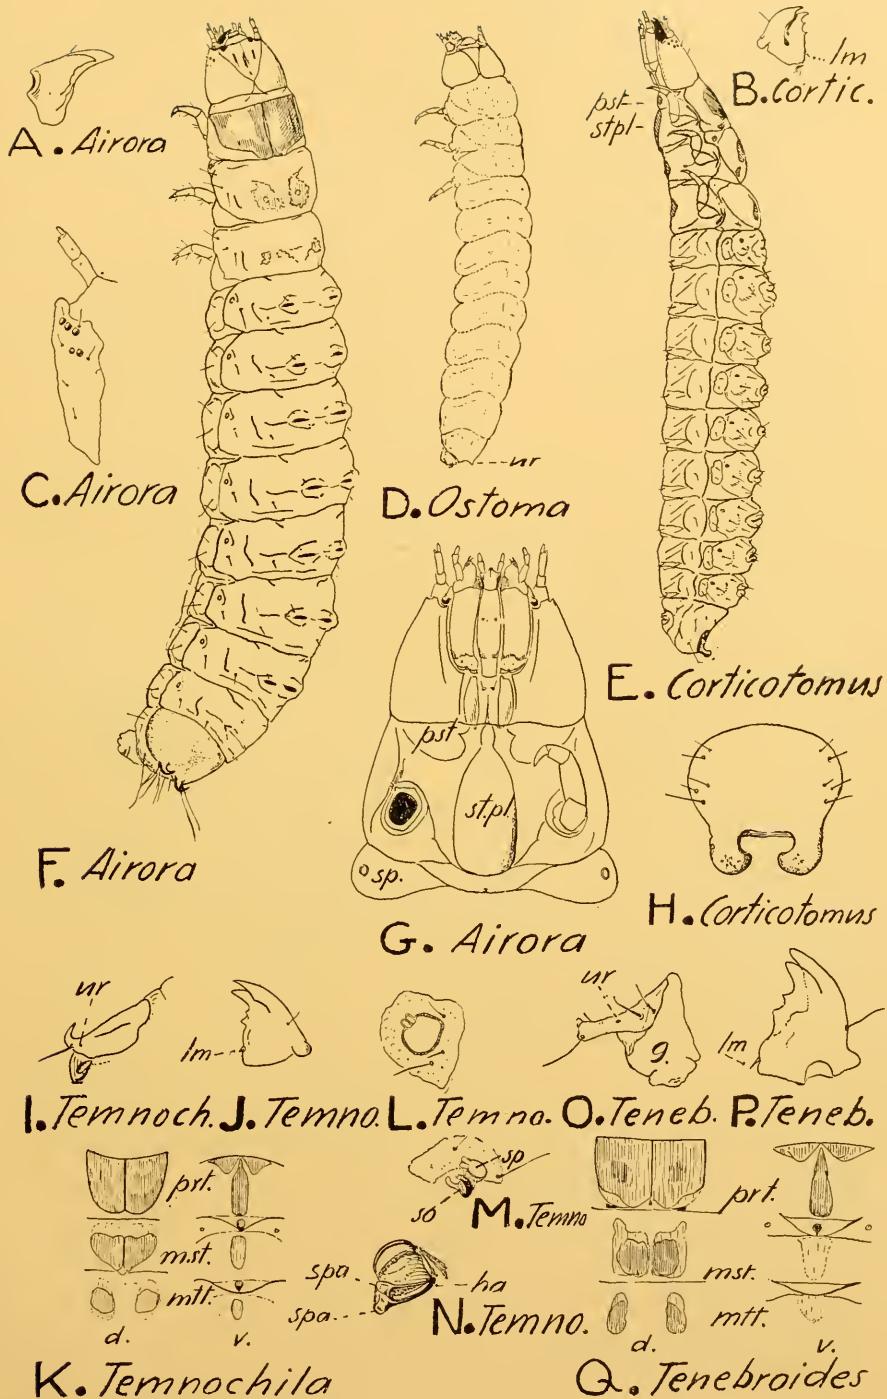

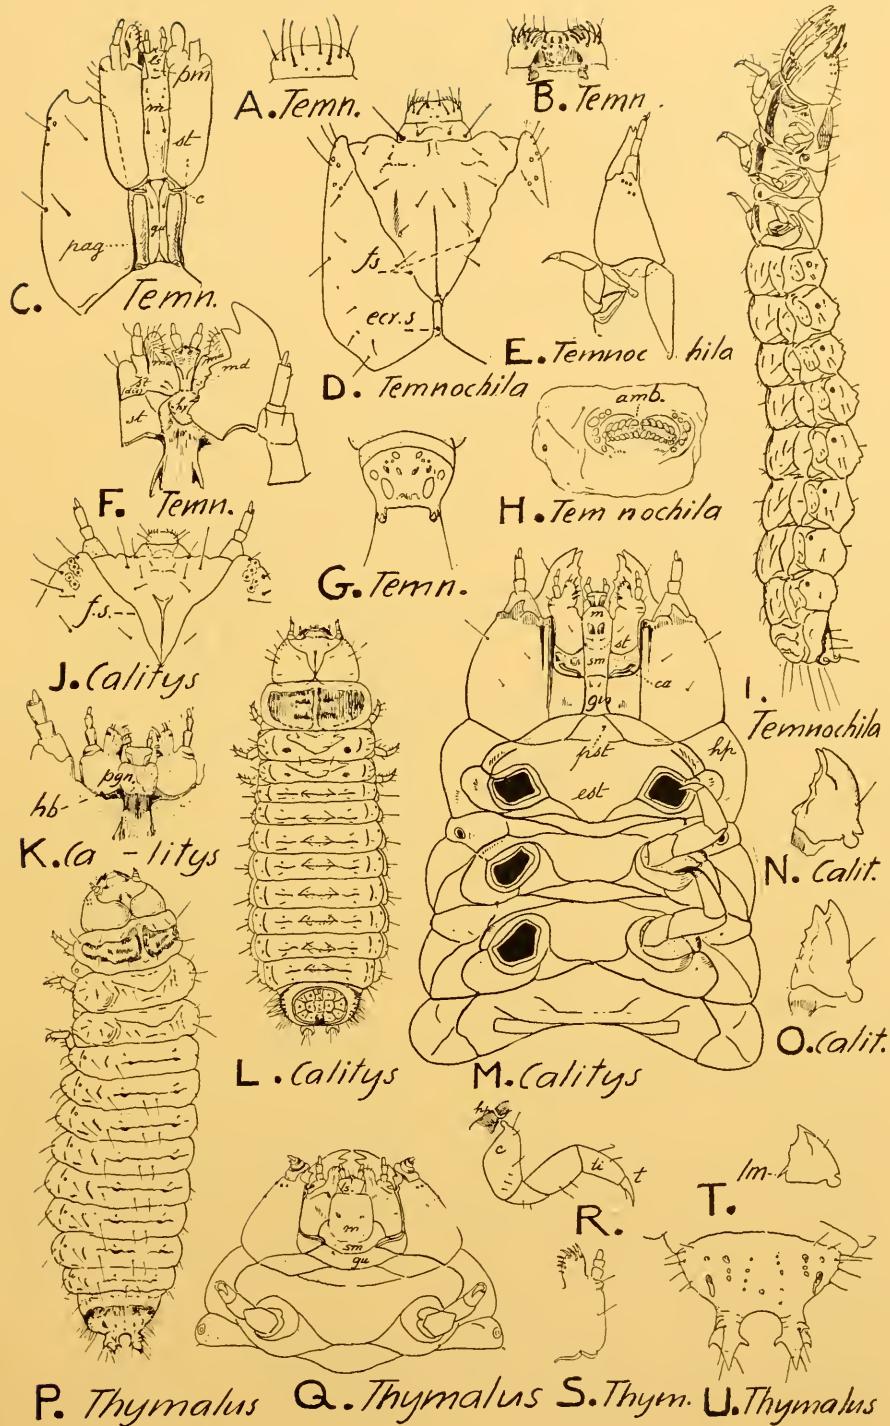

PLATE 94

Ostomidae-Tenebroidinae (*A-I*).*Ostomidae-Ostominae* (*J-U*)

- A. *Temnochila virescens* F. : Labrum.
 B. " " : Epipharynx.
 C. " " : Ventral mouthparts; pag, paragular plate; pm, prementum (fusion of the two stipites labii and the two palpigers).
 D. " " : Head; fs, frontal sutures; ecrs, epieranial suture.
 E. " " : Head and prothorax.
 F. " " : Antenna, mouthparts and hypopharynx. Dorsal view.
 G. " " : Ninth abdominal segment with urogomphi. Dorsal view.
 H. " " : Abdominal segment; amb, ambulatory wart. Dorsal view.
 I. " " : Larva. Ventro-lateral view.
 J. *Calytis seabra* Thunb. : Abdominal segment; amb, ambulatory wart.
 K. " " : Antenna, ventral mouthparts and hypopharynx; hb, hypopharyngeal bracon; pgn, maxillulae. Dorsal view.
 L. " " : Larva. Dorsal view.
 M. " " : Head, thorax and first abdominal segment. Ventral view.
 N. " " : Left mandible. Ventral view.
 O. " " : Left mandible. Buccal view.
 P. *Thymalus marginicollis* Chev. : Larva. Dorso-lateral view.
 Q. " " : Head and prothorax.
 R. *Thymalus limbatus* F. (Denmark) : Leg.
 S. " " : Right maxilla. Ventral view.
 T. " " : Left mandible. Ventral view.
 U. " " : Ninth abdominal segment with urogomphi. Dorsal view.

Ptinidae (A, B and E),
Anobiidae (C, D, F-N, X, Ae and Oe),
Bostrichidae (O-W, Y, Z)

- A. Niptus sp. (Larvae, pupae and imagines in *Desfontinea ilicifolia* Chili): Larva; ats, anal transverse sclerome.
 B. Ptinus fur L.: Ventral mouthparts.
 C. Nevermannia dorecatomoides Fisher (Costa Rica): Mesothoracic spiracle.
 D. " " : Right mandible.
 E. Ptinus fur : Mesothoracic spiracle.
 F. Nevermannia dorecatomoides : Head. Dorsal view.
 G. " " : Anal pad.
 H. " " : Larva. Lateral view.
 I. Lasioderma serricorne F. : Mandible.
 J. " " : Epipharynx (eph); labrum; clypeus, epipharynx, and antenna.
 K. " " : Head. Dorsal view.
 L. " " : Ventral mouthparts.
 M. Hedobia imperialis L. (Denmark) : Left maxilla; ma, undivided mala.
 N. Trichodesma klagesi Fall. : Left maxilla with mala divided into lacinia and galea.
 O. Scobicia declivis Lee., last instar : Epipharynx.
 P. " " " " : Longitudinal cut of inner wall of mandible.
 Q. " " first instar : Antenna, epipharynx and mouthparts.
 R. " " last instar : Left mandible.
 S. " " " " : Head. Dorsal view.
 T. " " first instar : Larva. Lateral view.
 U. " " " " : Tip of ninth abdominal segment. Dorsal view.
 V. " " last instar : Prothoracic spiracle.
 W. " " " " : Ventral mouthparts.
 X. Caenocara oculata Say : Left maxilla.
 Y. Scobicia declivis, last instar : Larva. Lateral view.
 Z. " " " " : Right maxilla.
 AE. Caenocara oculata : Right mandible.
 OE. " " : Larva. Lateral view.

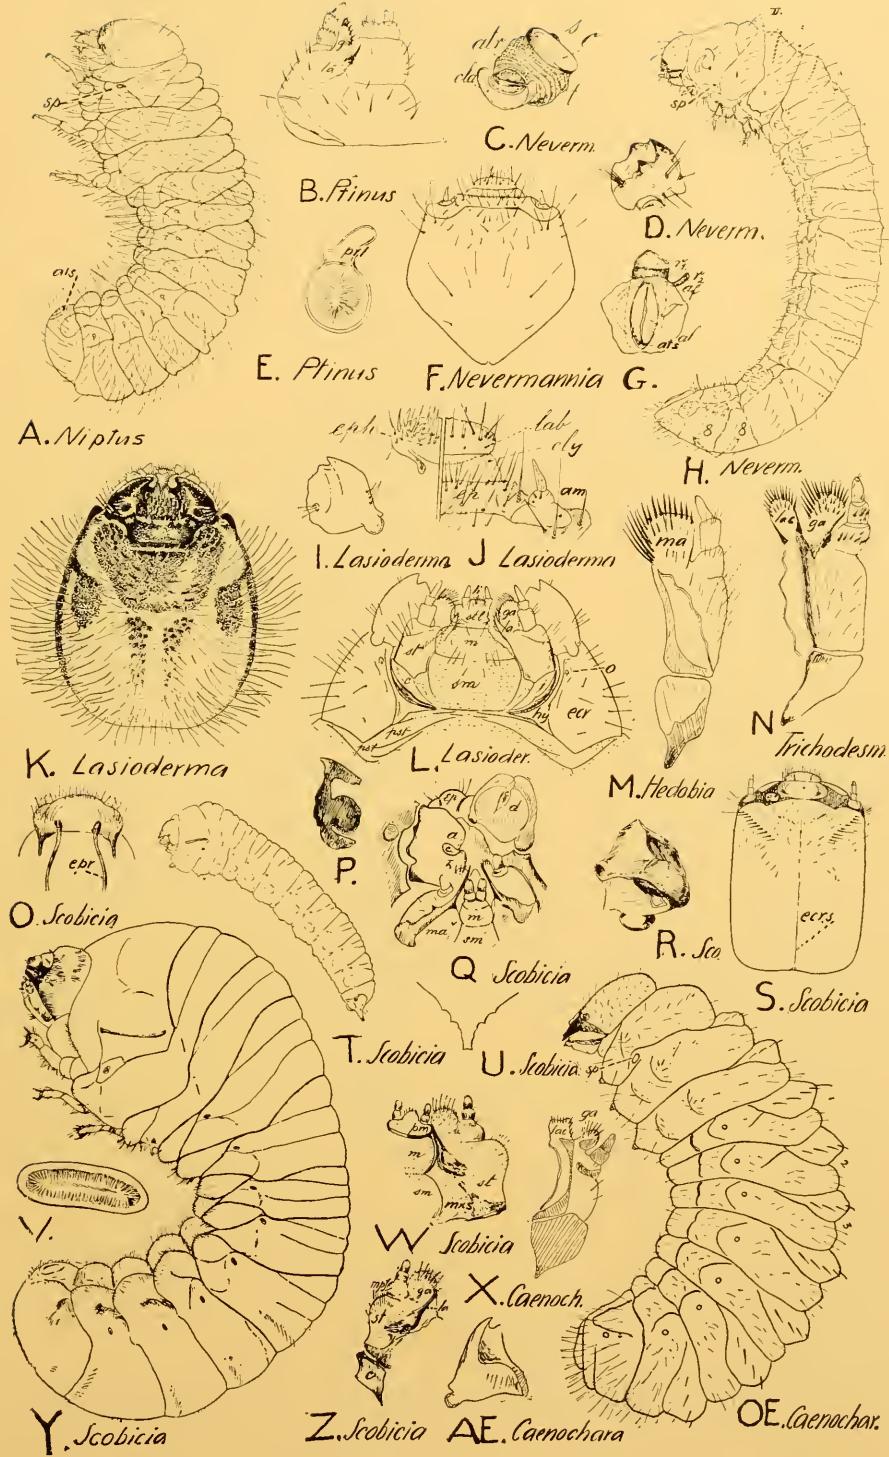

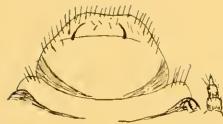

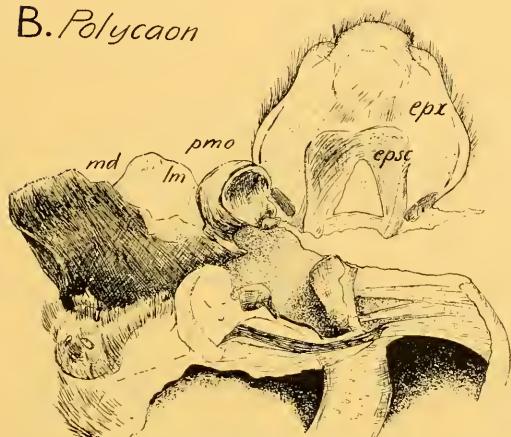

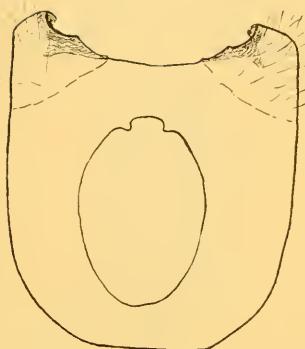

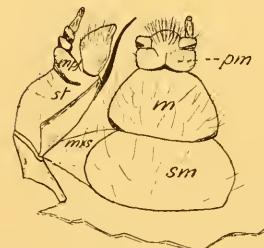

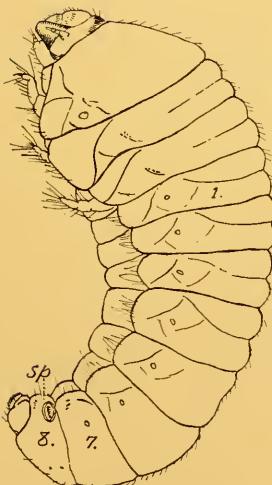

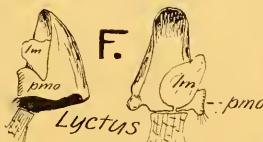

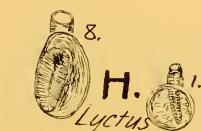

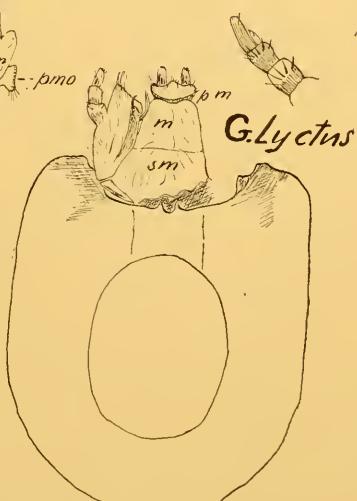

PLATE 102

Psoidae (A-E),*Lyctidae* (F-K)

- A. Stephanopachys pacificus Csy.: Labrum, clypeus, and antenna.
- B. Polyaon stouti Lee. : Labrum and clypeus.
- C. " " : Head capsule. Ventral view.
- D. " " : Interior of buccal region; epse, epipharyngeal sclerome; epx, epipharynx; lm, lacinia mandibulae; md, mandible; pmo, pseudomola, a big molar-like process from dorsal side of mandible.
- E. " " : Ventral mouthparts.
- F. Lyctus cavigollis Lee. : Right mandible; lm, lacinia mandibulae; pmo, pseudomola. Dorsal view (left); buccal view (right).
- G. " " : Antenna.
- H. " " : Eighth abdominal spiracle (left figure); first abdominal spiracle (right figure).
- I. " " : Larva. Lateral view.
- J. Lyctus cavigollis, first instar : Ninth abdominal segment with a pair of small urogomphi. Dorso-lateral view.
- K. " " , mature larva: Head and ventral mouthparts.

Bruchidae (= Mylabridae)

- A. *Caryedon fuscus* (Goeze) (= *Bruchus*
or *Pachymerus gonagra* F.) (Phil-
ippine Isl.) : Ocelli and antenna.
- B. *Pachymerus nucleorum* F. (Brazil) : Right mandible.
- C. *Caryedon fuscus* : Head. Dorsal view.
- D. " " : Ventral mouthparts; gl.,
glossa; li., ligula; lp.,
labial palpus; pgl.,
paraglossa; sm., sub-
mentum. Ventral
view.
- E. " " : Head. Ventral view.
- F. " " , first instar : Tibia and tarsus.
- G. *Pachymerus nucleorum* : Larva. Lateral view.
- H. *Bruchus* (= *Mylabris*) *obtectus* Say: Spiracle; atrium sepa-
rately to the right.
- I. " " : Labrum, elypterus and
epistoma.
- J. *Spermophagus hoffmanneggi* Gyll. : Anterior part of head.
Dorsal view.
- K. " " , first instar : Prothoracic dorsal X-
shaped plate in the
first bruchid instar
assisting it in enter-
ing the seeds of legu-
minous plants.
- L. " " , mature larva : Leg.
- M. " " , mature larva : Ventral mouthparts.
- N. " " , first instar : Leg.

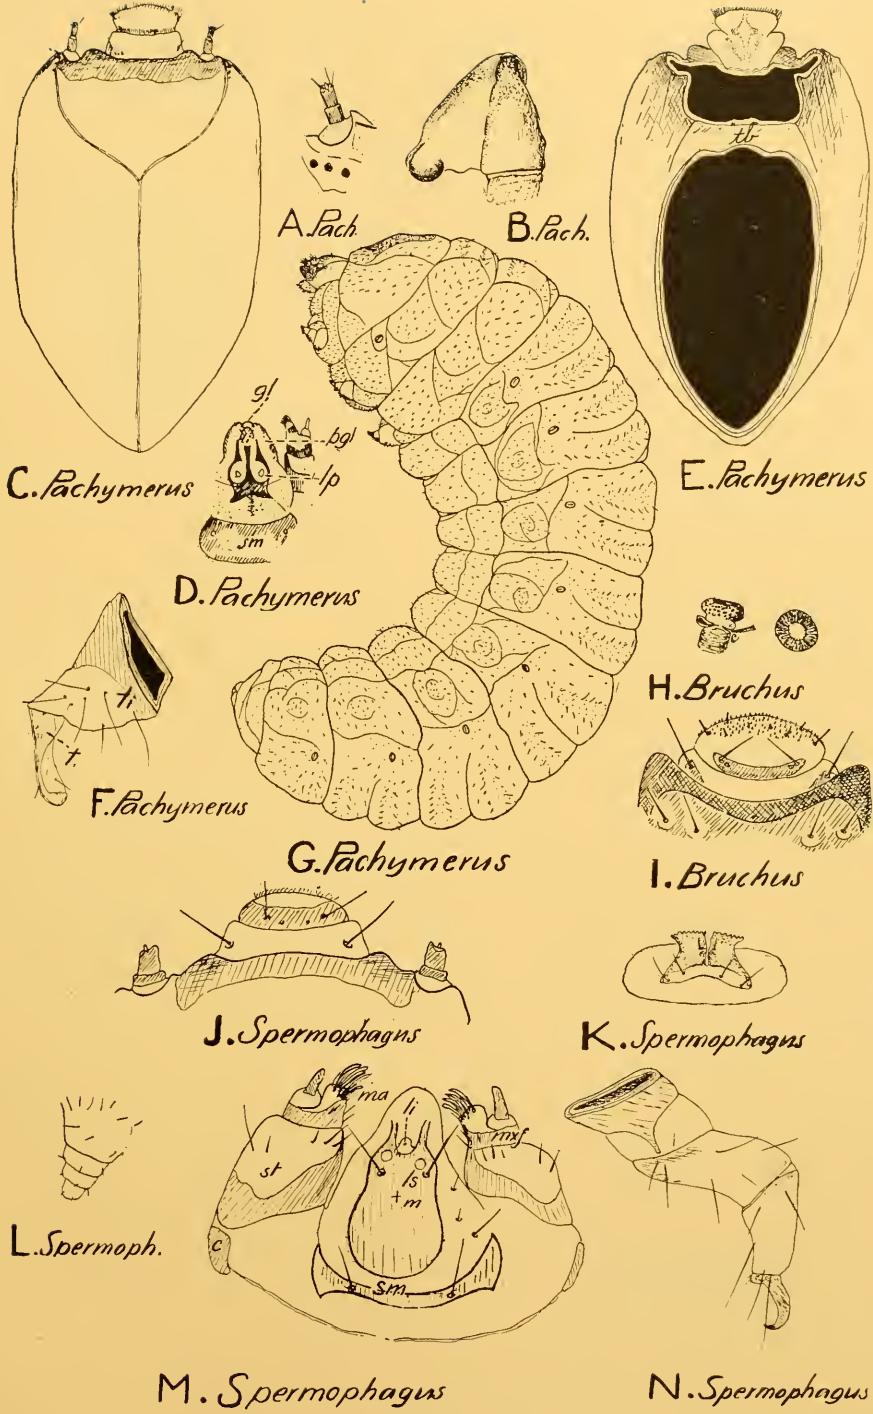

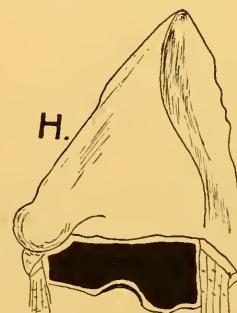

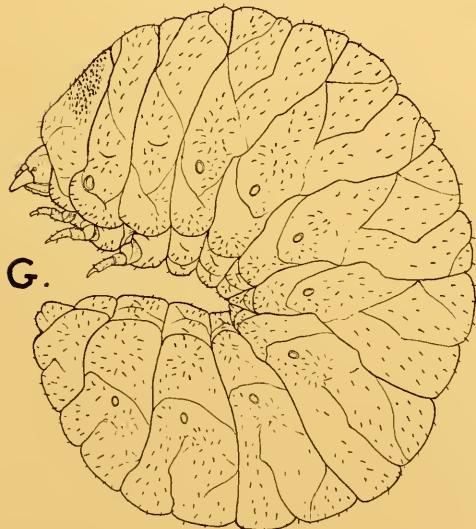

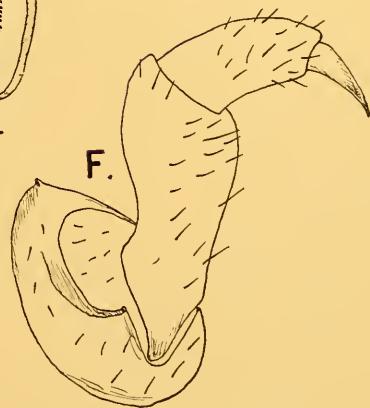

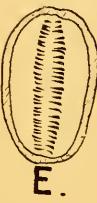

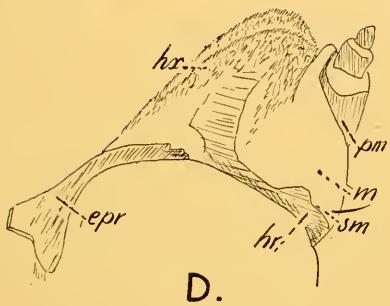

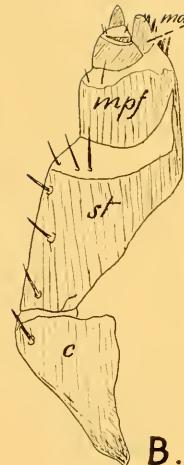

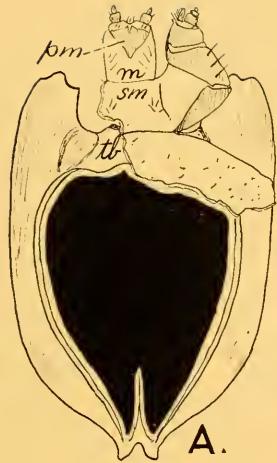

PLATE 104

Sagridae

- A. *Sagra femorata* Jac.
(Malleswar, Mysore State,
India) : Head. Ventral view.
- B. *Sagra femorata* Jac. : Right maxilla. Ventral view.
- C. " " : Head. Dorsal view.
- D. " " : Hypopharynx and labium. Lat-
eral view.
- E. " " : Abdominal spiracle, bilabiate type.
- F. " " : Leg.
- G. " " : Larva. Lateral view.
- H. " " : Right mandible. Ventral view.

Donaciidae

- A. Donacia sp. : Head. Lateral view.
 B. " " : Larva. Lateral view.
 C. " " : Head. Dorsal view.
 D. Donacia marginata Hoppe
 (Denmark) : Labrum, clypeus, epistoma.
 E. " " : Tip of antenna.
 F. " " : Right mandible. Dorsal view.
 G. Plateumaris braceata Scop.
 (Denmark) : Tip of maxilla. Dorsal view.
 H. Donacia crassipes F.
 (Denmark) : Distal part of maxilla; bl, blade;
 lac, lacinia; sty, stylus. Dorsal
 view. (Compare pl. 111 G;
 bl = *; sty = long seta).
 I. " " : Lacinia with stylus, and galea
 with blade. Ventral view.
 J. " " : Maxillary stipes with palpus.
 K. Donacia marginata : Mala; split open.
 L. Donacia marginata : Hook shaped eighth abdominal
 spiracle; showing opened tubes
 and atrium.
 M. " " : Hook shaped eighth abdominal
 spiracle; intact.
 N. " " : Longitudinal section of annular
 fourth abdominal spiracle and
 closing apparatus; ha, hard
 fold of closing apparatus
 against which soft fold from
 opposite wall of trachea is
 pressed when the closing muscle
 between the arms is contracted.
 O. Donacia sp. : Leg.
 P. " " : Ventral mouthparts.
 Q. " " : Cross-section of hook of eighth
 abdominal spiracle; bw, pro-
 longation from body wall.
 R. " " : Ventral mouthparts. Dorsal view.

Galerucidae-Galerucinae

- A. Galeruca tanaceti L. (Denmark) : Head. Dorsal view.
- B. Sermylassa halensis L. (Denmark) : Left mandible. Ventral view.
- C. Agelastica alni L. (Denmark) : Larva. Lateral view.
- D. Monoxia eonsputa Lee. : Spiracle.
- E. Agelastica alni : Left mandible. Ventral view.
- F. Galerucella luteola Müller : Larva. Dorsal view.
- G. Galeruca tanaceti : Larva. Lateral view.
- H. Monocesta coryli Say : Antenna and ocellus.
- I. " " : Left figure, showing laeinia, galea and hypopharynx facing the buccal cavity; right figure, showing galea, mentum, and labium viewed from below.
- J. " " : Leg.
- K. " " : Left mandible. Ventral view.
- L. " " : Tenth abdominal segment from below, showing anus in center and six anal lobes.
- M. " " : Larva. Lateral view.

LARVAL FORMS OF COLEOPTERA

PLATE 111

Galerucidae-Diabroticinae

- A. *Phyllobrotica quadrimaculata* L.
 (Denmark) : Head, prothorax and mesothorax. Dorsal view.
- B. " " " : Larva. Lateral view.
- C. *Diabrotica duodecimpunctata* Fab. : Left mandible. Ventral view.
- D. " " " : Head capsule. Dorsal view.
- E. *Phyllobrotica quadrimaculata* : End of abdomen. Dorsal view.
- F. *Diabrotica duodecimpunctata* : Pulvillus on posterior side of tarsungulus.
- G. " " " : Ventral mouthparts. Dorsal view (left figure); ventral view (right figure).
- H. *Diabrotica longicornis* Say : End of abdomen. Dorsal view.
- I. *Diabrotica duodecimpunctata* : End of abdomen. Dorsal view.
- J. *Diabrotica vittata* F. : End of abdomen. Lateral view.
- K. *Diabrotica duodecimpunctata* : Anterior part of larva. Lateral view.
- L. *Diabrotica vittata* : End of abdomen. Dorsal view.
- M. *Exosoma lusitanica* L. (Marocco) : Anterior part of larva. Lateral view.

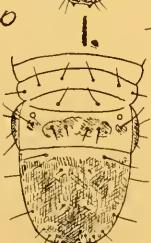

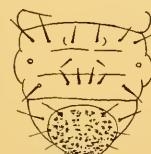

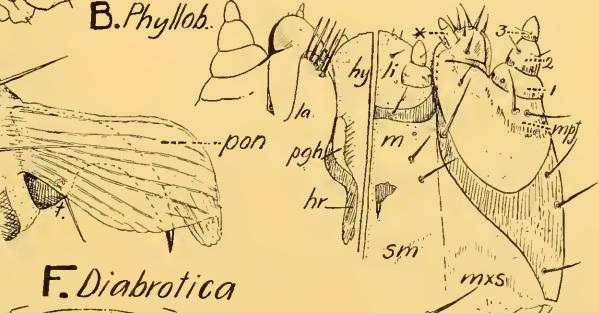

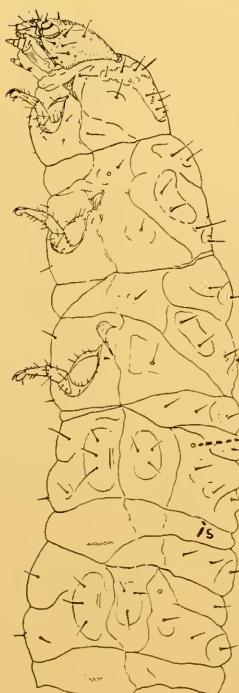

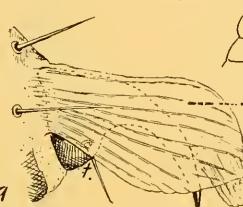

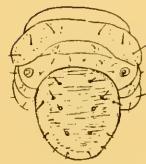

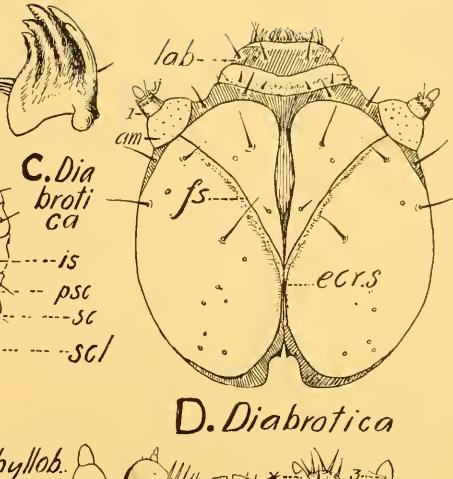

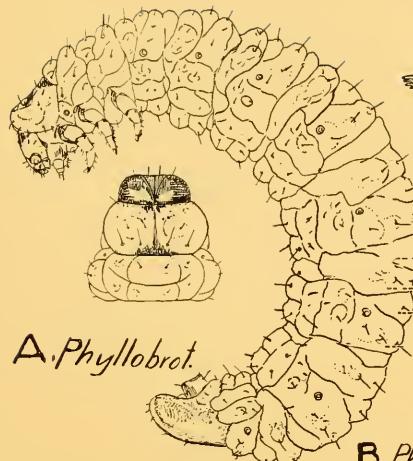

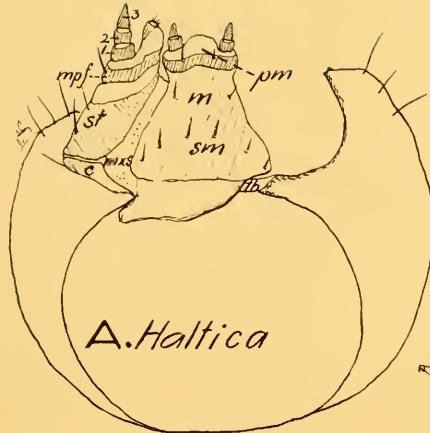

PLATE 112

Galerucidae-Halticinae

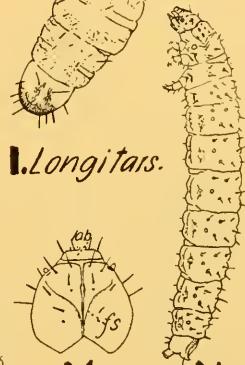

- A. *Haltica bimarginata* Say : Head. Ventral view.
 B. " " : Left maxilla.
 C. *Longitarsus mentaphagus* Gentner : Antenna.
 D. " " : Left mandible.
 E. " " : Peglike appendix of galea.
 F. " " : Distal end of maxilla.
 G. *Chaetocnema* (denticulata Ill.?) : Anterior part of larva.
 H. *Longitarsus mentaphagus* : Anterior part of larva.
 I. " " : Larva. Dorsal view.
 J. *Phyllotreta armoraciae* Koch (Denmark) : Anterior part of larva.
 K. *Chaetocnema* (denticulata ?) : Larva. Dorsal view.
 L. *Blepharida rhois* Forst. : Spiraele.
 M. *Psylliodes chrysocephala* L. : Head. Dorsal view.
 N. " " : Larva. Lateral view.
 (Copy from figure by George H. Carpenter, 1906).
 O. *Blepharida rhois* : Right maxilla.
 P. *Phyllotreta armoraciae* : Posterior end of body.
 Dorsal view.
 Q. *Blepharida rhois* : Mandible.
 R. " " : Larva; notice the dorsal position of anus as in *Crioceris* (pl. 109G).
 R.* " " : Sucking disk; without an anal opening in the center.

PLATE 113

Galerucidae-Halticinae

A.	Oedionychis gibbitarsa Say	:	Antenna; a, ring shaped sclerome at base of the tactile appendix; at, membranous part of tactile appendix; b, first antennal joint; c, rudiment of second joint.
B.	" "	:	Tip of labium.
C.	" "	:	Distal part of maxilla.
D.	" "	:	Eighth and ninth abdominal segments. Dorsal view.
E.	" "	:	Larva. Lateral view.
F.	" "	:	Mandible. Ventral view.
G.	" "	:	Last abdominal segments. Ventral view.
H.	Disonycha xanthomelaena Dalm.	:	End of body. Lateral view.
I.	Phydanis bicolor Horn.	:	Head. Dorsal view.
J.	Mantura floridana Cr.	:	Left mandible.
K.	" "	:	Tip of maxillary mala with peg indicating galea, lacinia absent.
L.	Phydanis bicolor	:	Eighth and ninth abdominal segments. Dorsal view.
M.	Mantura floridana	:	Tip of leg.
N.	Phydanis bicolor	:	Larva. Lateral view.
O.	Mantura floridana	:	Larva. Lateral view.
P.	" "	:	Ventral mouthparts.
Q.	" "	:	Larva. Dorsal view.
R.	Argopistes scyrtooides Lec.	:	Mandible. Buccal view.
S.	" "	:	Head. Dorsal view.
T.	" "	:	Thorax and first abdominal segment. Dorsal view.
U.	" "	:	Thorax and first abdominal segment. Ventral view.
V.	" "	:	End of body. Ventral view.
X.	" "	:	Ventral mouthparts.

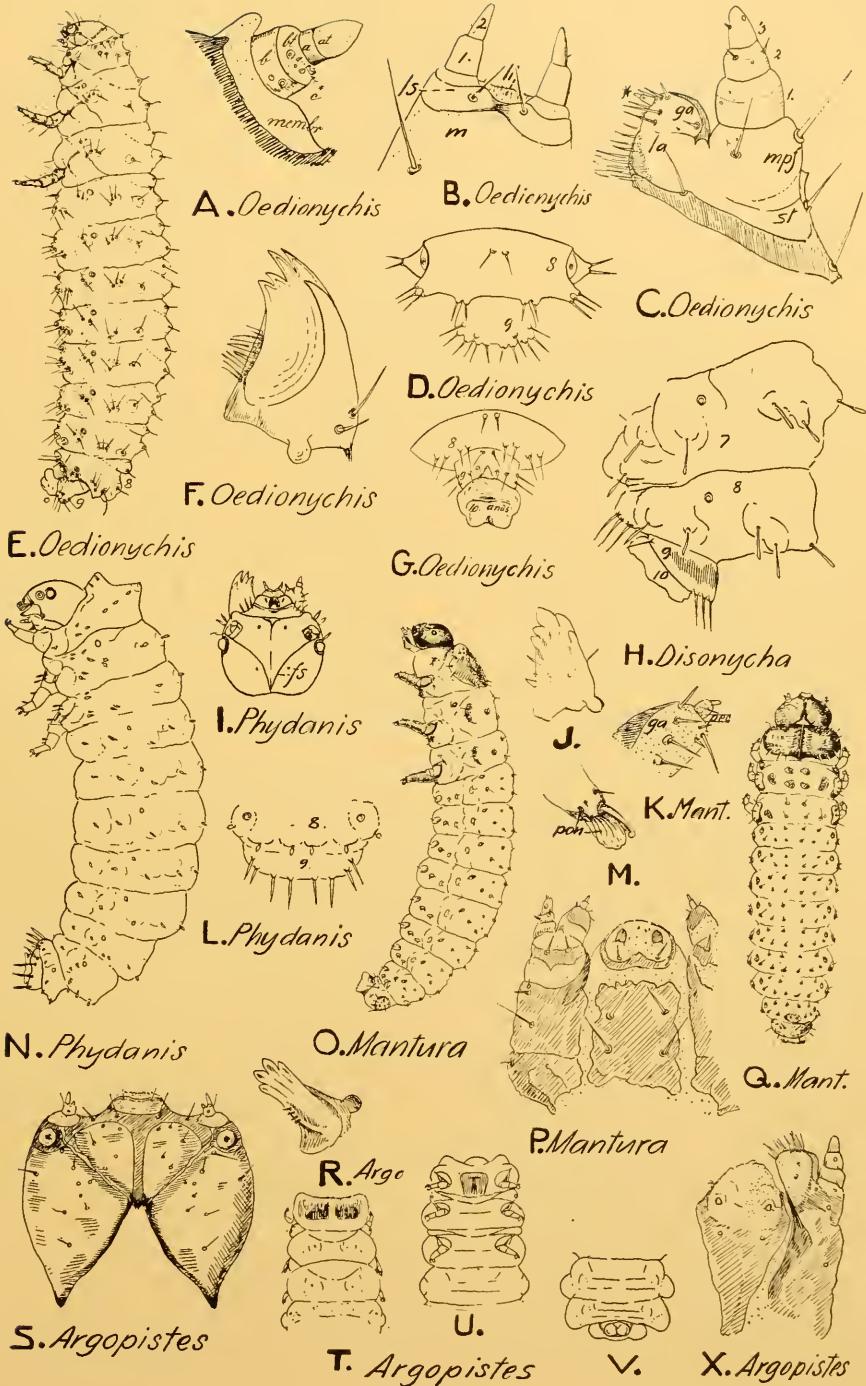

PLATE 114

Galerucidae-Halticinae

- A. Dibolia cynoglossi Koch
(Denmark) : Antenna.
- B. " " : Anterior part of body. Dorsal view.
- C. " " : Left mandible. Ventral view.
- D. " " : Posterior end of body. Dorsal view.
- E. Dibolia borealis Chev. : Posterior end of body. Dorsal view.
- F. Dibolia cynoglossi : Anterior end of body. Ventral view.
- G. " " : Head. Dorsal view.
- H. Dibolia borealis : Head. Ventral view.
- I. Sphaeroderma testaceum F.
(Denmark) : Head; notice shape of frons and large ocelli. Dorsal view.
- J. Sphaeroderma testaceum F. : Leg.
- K. " " : Antenna.
- L. " " : Larva. Dorsal view.
- M. " " : Left mandible. Ventral view.
- N. " " : Ventral mouthparts. Ventral view.
- O. " " : Mala maxillaris.

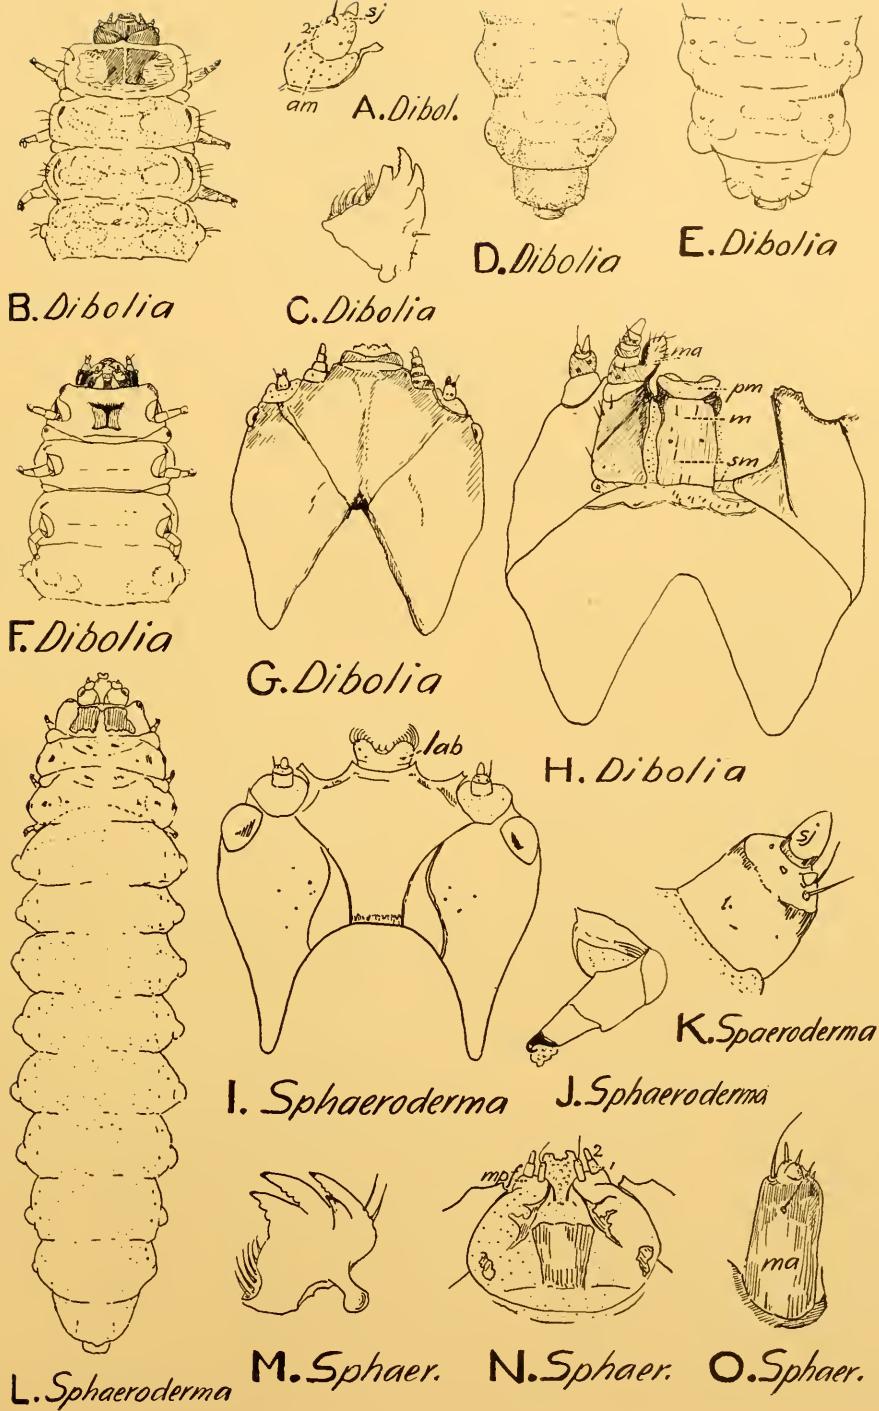

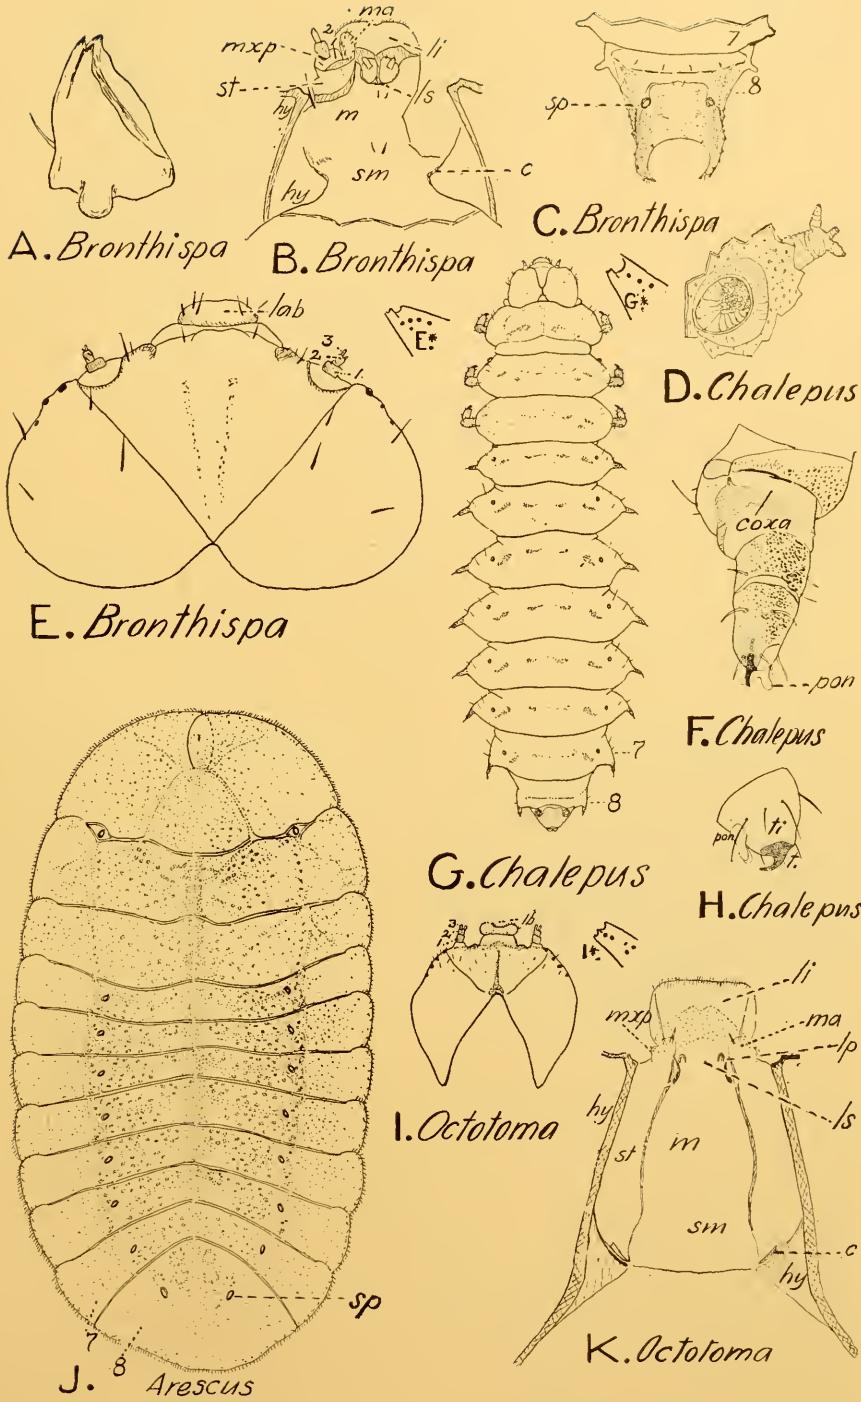

PLATE 115

Hispidae

- A. Bronthispa frogatti Sharp (Solomon Isl.) : Right mandible. Ventral view.
- B. " " " : Ventral mouthparts. Ventral view.
- C. " " " : Posterior end of abdomen. Dorsal view.
- D. Chalepus ater Weise : Eighth abdominal spiracle.
- E. Bronthispa frogatti : Head. Dorsal view.
- E.* " " " : Ocelli. Lateral view.
- F. Chalepus ater : Mesothoracic leg.
- G. " " " : Larva. Dorsal view.
- G.* " " " : Ocelli. Lateral view.
- H. " " " : Distal end of leg.
- I. Octotoma plicatula F. : Head. Dorsal view.
- I.* " " " : Ocelli. Lateral view.
- J. Arecesus monoceros Oliv. (Porto Bello, Panama) : Larva. Dorsal view.
- K. Octotoma plicatula : Ventral mouthparts. Ventral view.

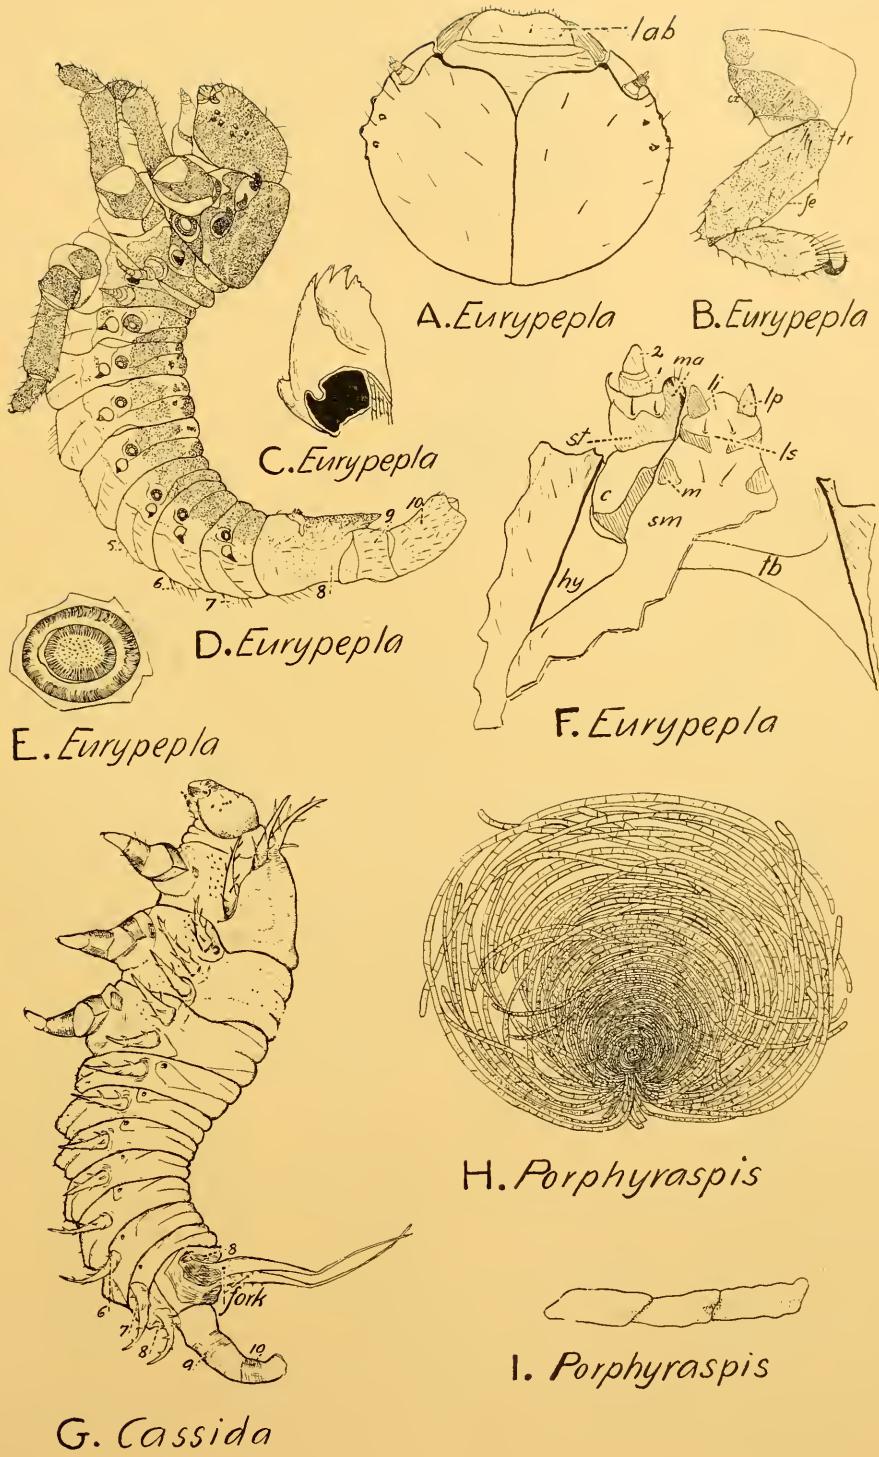

LARVAL FORMS OF COLEOPTERA

PLATE 120

Apionidae (A-D),

Circulionidae-Circulioninae (E-G)

- A. *Podapion gallicola* Riley : Head. Dorsal view.
- B. " " : Prementum with labial palpi.
- C. " " : Larva. Lateral view.
- D. " " : Right maxilla. Ventral view.
- E. *Prionomerus calcaneatus* Say : Larva; lpr, lateral process.
Dorsal view.
- F. " " : Larva. Lateral view.
- G. *Cionus serophulariae* L.
(Denmark) : Larva. Ventral view.

Podapion

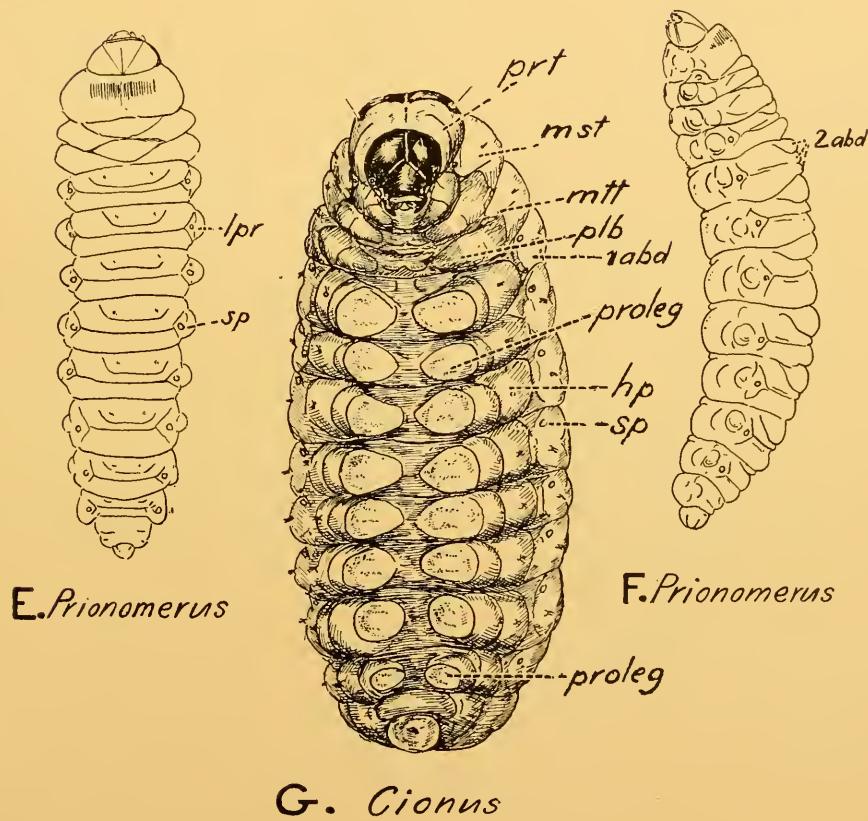

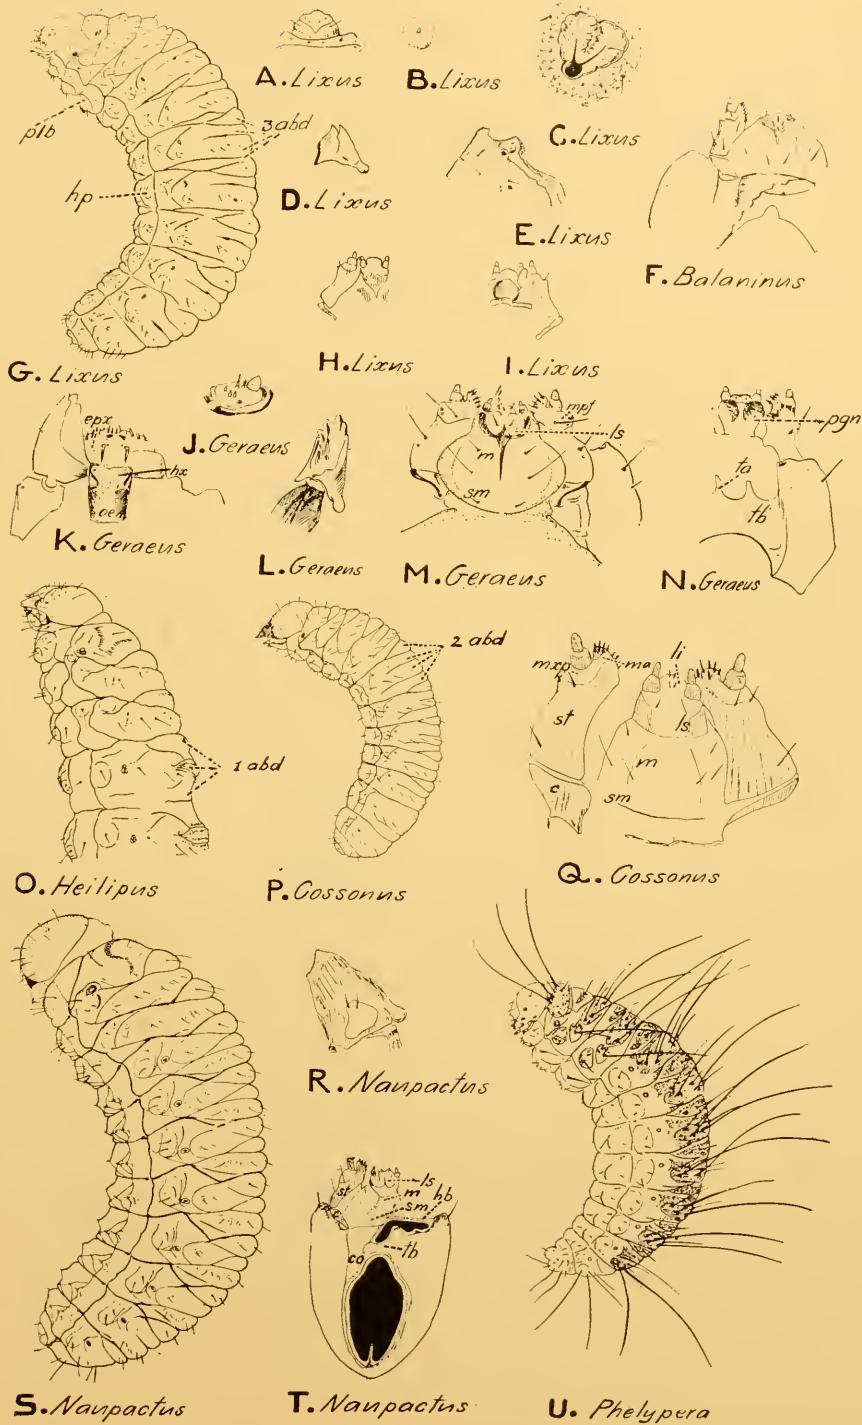

PLATE 121

Curculionidae

- A. *Lixus serobicollis* Boh. : Labrum and clypeus.
 B. " " : Antenna.
 C. " " : Abdominal spiracle.
 D. " " : Left mandible. Ventral view.
 E. " " : Antenna and two ocelli.
 F. *Balaninus* sp. : Ventral mouthparts and tentorialium. Ventral view.
 G. *Lixus serobicollis* : Larva. Lateral view.
 H. " " : Ventral mouthparts. Ventral view.
 I. " " : Ventral mouthparts. Dorsal view.
 J. *Geraeus penicellus* Herbst. : Antenna.
 K. " " : Epipharynx, hypopharynx, mandible from below, and oesophagus.
 L. " " : Mandible. Buccal view.
 M. " " : Ventral mouthparts. Ventral view.
 N. " " : Ventral mouthparts and hypopharyngeal region.
 O. *Heilipus perseae* Barber
 (Panama, C. Z.): Anterior part of larva. Lateral view.
 P. *Cossonus* sp. (Hopk. U. S.)
 10079j: Larva. Lateral view.
 Q. " " : Ventral mouthparts. Ventral view.
 R. *Naupactus* sp. (Chili) : Right mandible. Exterior view.
 S. " " : Larva. Lateral view.
 T. " " : Head; co, skin connecting head and prothorax. Ventral view.
 U. *Phelypera distigma* Boh.
 (Guatemala): Larva. Lateral view.

LARVAL FORMS OF COLEOPTERA

PLATE 122

Curculionidae-Lissorhoptrinae

- A. *Lissorhoptrus simplex* Say : Head. Lateral view.
 B. " " : Larva, showing a pair of hook-shaped spiracles on the back of second to seventh abdominal segments. Lateral view.
 C. " " : Apex of dorsal spiracular hook.
 D. " " : Epipharynx.
 E. " " : A pair of spiracular hooks. Dorsal view.
 F. " " : Eighth abdominal spiracle; not freely projecting.
 G. " " : Antenna.
 H. " " : Left mandible. Ventral view.
 I. " " : Right maxilla. Buccal view.
 J. " " : Spiracular hooks; tracheal branch to spiracle (spr); tracheal stem and closing apparatus.
 K. " " : Head. Dorsal view.
 L. " " : Head. Ventral view.
 M. " " : Ventral mouthparts.
 N. " " : Hypopharyngeal region.
 O. " " : Cocoon with mud cover removed.
 P. " " : Epidermis from which the cocoon is exuded.
 Q. " " : Larva. Dorsal view.
 R. " " : Two cocoons; one with mud cover removed from upper half.
 S. " " : Cocoon opened to show the larva in position and completely clean after having exuded the cocoon; notice the breathing hole gnawn into the submerged rice stem.
 T. " " : Hole in stem and cocoon.
 U. " " : Hole on side of stem.
 V. " " : Cocoon showing breathing (bh) and emergence (eh) holes.

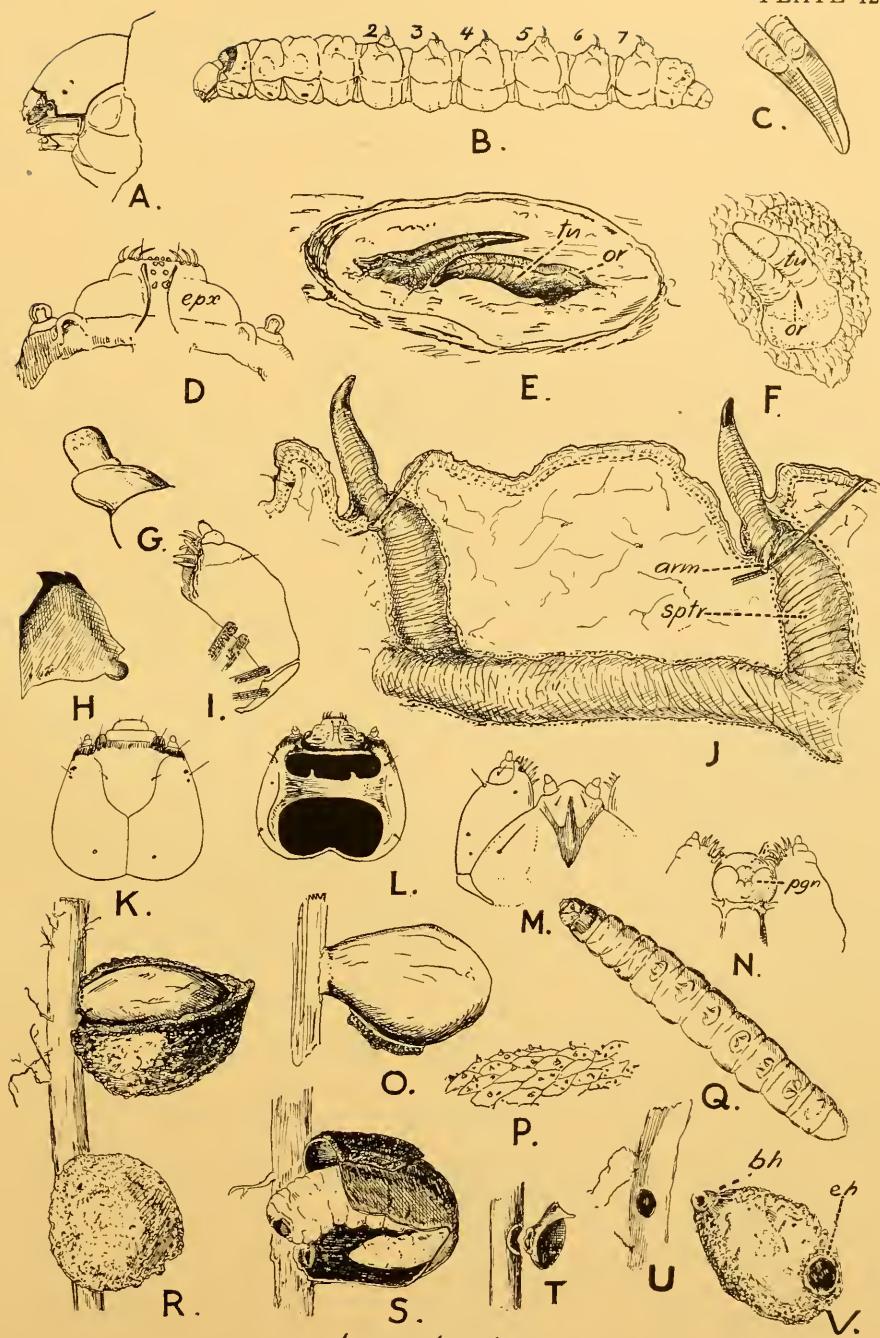

*Lissorhoptrus*

LIST OF ERRATA

(The changes should be made before using the book.)

Page 8, line 9. Insert before "the series Bostrichoidea": and from hypothetical cleroid ancestors or possibly directly from the Byrrhoidea may originate.

Page 8, line 27. For Melandryidae read: Synchroidae.

Page 9, line 7. For paragnathal read: maxillular.

Page 11, line 5. For individually read: usually.

Page 11, footnote 8. Insert before "some": Hydroscapha.

Page 12, footnote 14. For the entire footnote as it stands read: The larvae of the Catogenidae (pl. 33) are readily distinguished by their physogastric body, the larvae of the Epilachninae (pl. 38) by long, branched dorsal and lateral spines and by multicuspitate mandibular apices in the mature larvae, and the larvae of the Lamiinae (pl. 100) by their elongate, fleshy body with short or no legs and by the presence of a broad, transverse bridge closing the headcapsule behind protracted ventral mouthparts.

Page 18, line 42. For Driptinae read: Dryptinae.

Page 20, section 6. For Driptinae read: Dryptinae.

Page 20, section 9. Insert after "simple": or with a small accessory process at base.

Page 21, line 4. For Maronetes read: Maronetus.

Page 24, line 12. Read: urogomphi almost absent
Cybisterinae.

Page 29, line 5. For Megarthus read: Megarhrus.

Page 36, section 22, second part. Omit: " , or large, elongate trapezoidal, movable, and with posterior condyle."

Page 38, line 9. For Murmediidae read: Mirmidiidae.

Page 38, footnote 49. For Murmediidae read: Mirmidiidae.

Page 39, section 37. For Anaspidae read: Anaspidae.

Page 47, section 4. For Homolisidae read: Homalisidae.

Page 47, section 5. For Malthinae read: Malthininae.

Page 54, section 26. For Cetoniini read: Cetoniini.

Page 59, footnote 72. For Horniiae read: Horinae.

Page 60, line 13. Insert after "melandryid genera": as well as to the Ciidae.

Page 61, section 3. For "clypeus filling space" read: clypeus never filling space.

Page 70. For Driptinae read: Dryptinae.

Page 76. For Malthinae read: Malthininae.

Page 124. Discard figure H on plate 19 as it does not show the serrations with which the mandible is armed on the dorsal and ventral margins of the inneredge.

Page 130, figures B and C. Insert after "head": ; ang. f. angulus frontalis.

LARVAL FORMS OF COLEOPTERA

Page 138, figure B. Insert after "Head": ; a, articulating membrane of maxilla.

Page 180, line 2. For Anaspidae read: Anaspidae.

Page 200, figures K to N. For Gnathocerus cornutus F. read: *Uloma imberbis* Lec.

Page 227. Omit figures D and E. See figures by R. E. Blackwelder in Pan-Pacific Entomologist pp. 139-142, vol. 6, 1930.

Page 266, figure W. For Aspectus read: Apsectus.

ADDENDA

Page 15, footnote 20. For the entire footnote as it stands read: The systematic position of this series is uncertain. Its larval form approaches in important characters the larvae of the cecujoid family Oedemeridae but also appears to converge toward the larval form of the ancient suborder Archostemata. Giving serial rank to the group is in accord with the generally accepted views in regard to its phylogeny but from the larval form it could with equal rights be considered a mere family, Lymexylidae, of the series Cucujoidea. This latter classification can be expressed by altering and somewhat simplifying the parts of the keys relevant to the matter in the following way:

First alteration

Page 12. For section 10 as it stands read:

- | | |
|--|----|
| 10. Distinct gula or gular structure present or absent; when absent, with mandibles possessing mola, or lacinia mandibulae, or retinaculum, or a long brush of hairs posteriorly on the inner margin, or extraordinary structures, except a pseudomola | 11 |
| Distinct gula or gular suture always absent, mandible either simple or possessing a pseudomola | 20 |

Second alteration

Page 14. For section 18 as it stands read:

- | | |
|--|----|
| 18. Ventral mouthparts as a rule retracted; when protracted ¹⁷ possessing a mandible with either molar part, or retinaculum, or other appendices | 19 |
| Ventral mouthparts always protracted; mandible always simple without molar part, retinaculum or other appendices. (Head-capsule closed posteriorly by a broad, transverse bridge separating the subfacial region of head from ventral region of prothorax) | |

Cerambycoidea (p. 60)
(except cerambycoid subfamily *Disteninae*, p. 15, line 4 and p. 62.)

LARVAL FORMS OF COLEOPTERA

19. Maxillary mala simple or terminally slightly indented
..... *Cucujoidea* (p. 33)
Maxillary mala divided into a lacinia and a lobe-shaped
galea *Platystomoidea* (p. 66)

Third alteration

Page 15. Section 23 to be completely eliminated.

Fourth alteration

Page 40. For section 44 as it stands read:

44. Paired urogomphi present 45
Paired urogomphi absent 44b
44b. Ninth abdominal segment heavily sclerotized, either
cylindrical with obliquely truncate end (*Lymexylinae*), or elongate conical (*Hylecoetinae*)
..... *Lymexylidae* (pl. 124 A-M)
Ninth abdominal segment without sclerome
..... *Oedemeridae-Oedemerinae* (pl. 51 A-F)

Page 69. Insert:
